Table of Contents

I. Spring Boot Documentation	1
1. About the Documentation	2
2. Getting Help	3
3. First Steps	4
4. Working with Spring Boot	5
5. Learning about Spring Boot Features	6
6. Moving to Production	7
7. Advanced Topics	8
II. Getting Started	9
8. Introducing Spring Boot	. 10
9. System Requirements	. 11
9.1. Servlet Containers	. 11
10. Installing Spring Boot	. 12
10.1. Installation Instructions for the Java Developer	. 12
Maven Installation	. 12
Gradle Installation	. 13
10.2. Installing the Spring Boot CLI	. 14
Manual Installation	. 14
Installation with SDKMAN!	. 14
OSX Homebrew Installation	. 15
MacPorts Installation	. 15
Command-line Completion	. 15
Quick-start Spring CLI Example	. 16
10.3. Upgrading from an Earlier Version of Spring Boot	. 16
11. Developing Your First Spring Boot Application	. 17
11.1. Creating the POM	. 17
11.2. Adding Classpath Dependencies	. 18
11.3. Writing the Code	. 19
The @RestController and @RequestMapping Annotations	. 19
The @EnableAutoConfiguration Annotation	
The "main" Method	. 20
11.4. Running the Example	
11.5. Creating an Executable Jar	. 20
12. What to Read Next	. 22
III. Using Spring Boot	. 23
13. Build Systems	. 24
13.1. Dependency Management	. 24
13.2. Maven	24
Inheriting the Starter Parent	. 25
Using Spring Boot without the Parent POM	. 25
Using the Spring Boot Maven Plugin	
13.3. Gradle	26
13.4. Ant	26
13.5. Starters	. 27
14. Structuring Your Code	. 33
14.1. Using the "default" Package	. 33
14.2 Locating the Main Application Class	. 33

15.	Configuration Classes	35
	15.1. Importing Additional Configuration Classes	
	15.2. Importing XML Configuration	
16	Auto-configuration	
10.	16.1. Gradually Replacing Auto-configuration	
	16.2. Disabling Specific Auto-configuration Classes	
17		
	Spring Beans and Dependency Injection	
	Using the @SpringBootApplication Annotation	
19.	Running Your Application	
	19.1. Running from an IDE	
	19.2. Running as a Packaged Application	
	19.3. Using the Maven Plugin	
	19.4. Using the Gradle Plugin	40
	19.5. Hot Swapping	40
20.	Developer Tools	41
	20.1. Property Defaults	41
	20.2. Automatic Restart	42
	Logging changes in condition evaluation	43
	Excluding Resources	43
	Watching Additional Paths	43
	Disabling Restart	43
	Using a Trigger File	
	Customizing the Restart Classloader	
	Known Limitations	
	20.3. LiveReload	
	20.4. Global Settings	
	20.5. Remote Applications	
	Running the Remote Client Application	
	Remote Update	
24	•	
	Packaging Your Application for Production	
	What to Read Next	
•	g Boot features	
23.	SpringApplication	
	23.1. Startup Failure	
	23.2. Customizing the Banner	
	23.3. Customizing SpringApplication	
	23.4. Fluent Builder API	
	23.5. Application Events and Listeners	54
	23.6. Web Environment	55
	23.7. Accessing Application Arguments	55
	23.8. Using the ApplicationRunner or CommandLineRunner	55
	23.9. Application Exit	56
	23.10. Admin Features	56
24.	Externalized Configuration	58
	24.1. Configuring Random Values	
	24.2. Accessing Command Line Properties	
	24.3. Application Property Files	
	24.4. Profile-specific Properties	
	24.5. Placeholders in Properties	
	24.6. Using YAML Instead of Properties	
	2 1.0. Comy 17 title indicad of 1 Topolitics	J2

	Loading YAML	62
	Exposing YAML as Properties in the Spring Environment	63
	Multi-profile YAML Documents	63
	YAML Shortcomings	64
	Merging YAML Lists	64
	24.7. Type-safe Configuration Properties	65
	Third-party Configuration	68
	Relaxed Binding	68
	Properties Conversion	70
	@ConfigurationProperties Validation	70
	@ConfigurationProperties vs. @Value	71
25.	Profiles	72
	25.1. Adding Active Profiles	72
	25.2. Programmatically Setting Profiles	73
	25.3. Profile-specific Configuration Files	73
26.	Logging	74
	26.1. Log Format	74
	26.2. Console Output	74
	Color-coded Output	75
	26.3. File Output	76
	26.4. Log Levels	
	26.5. Custom Log Configuration	77
	26.6. Logback Extensions	79
	Profile-specific Configuration	79
	Environment Properties	79
27.	Developing Web Applications	81
	27.1. The "Spring Web MVC Framework"	81
	Spring MVC Auto-configuration	81
	HttpMessageConverters	
	Custom JSON Serializers and Deserializers	
	MessageCodesResolver	83
	Static Content	
	Welcome Page	85
	Custom Favicon	
	Path Patching and Content Negotiation	
	ConfigurableWebBindingInitializer	
	Template Engines	
	Error Handling	
	Custom Error Pages	
	Mapping Error Pages outside of Spring MVC	
	Spring HATEOAS	
	CORS Support	
	27.2. The "Spring WebFlux Framework"	
	Spring WebFlux Auto-configuration	
	HTTP Codecs with HttpMessageReaders and HttpMessageWriters	
	Static Content	
	Template Engines	
	Error Handling	
	Custom Error Pages	
	27.3. JAX-RS and Jersey	93

	27.4. Embedded Servlet Container Support	94
	Servlets, Filters, and listeners	94
	Registering Servlets, Filters, and Listeners as Spring Beans	95
	Servlet Context Initialization	95
	Scanning for Servlets, Filters, and listeners	95
	The ServletWebServerApplicationContext	95
	Customizing Embedded Servlet Containers	96
	Programmatic Customization	96
	Customizing ConfigurableServletWebServerFactory Directly	97
	JSP Limitations	97
28.	Security	98
29.	MVC Security	99
30.	WebFlux Security	100
	30.1. OAuth2	100
	Client	100
	30.2. Actuator Security	101
31.	Working with SQL Databases	
	31.1. Configure a DataSource	
	Embedded Database Support	
	Connection to a Production Database	
	Connection to a JNDI DataSource	
	31.2. Using JdbcTemplate	
	31.3. JPA and "Spring Data"	
	Entity Classes	
	Spring Data JPA Repositories	
	Creating and Dropping JPA Databases	
	Open EntityManager in View	
	31.4. Using H2's Web Console	
	Changing the H2 Console's Path	
	31.5. Using jOOQ	
	Code Generation	
	Using DSLContext	
	jOOQ SQL Dialect	
	Customizing jOOQ	
32.	Working with NoSQL Technologies	
	32.1. Redis	
	Connecting to Redis	
	32.2. MongoDB	
	Connecting to a MongoDB Database	
	MongoTemplate	
	Spring Data MongoDB Repositories	
	Embedded Mongo	
	32.3. Neo4j	
	Connecting to a Neo4j Database	
	Using the Embedded Mode	
	Neo4jSession	
	Spring Data Neo4j Repositories	
	Repository Example	
	32.4. Gemfire	
	32.5. Solr	
		_

	Connecting to Solr	
	Spring Data Solr Repositories	115
	32.6. Elasticsearch	116
	Connecting to Elasticsearch by Using Jest	116
	Connecting to Elasticsearch by Using Spring Data	116
	Spring Data Elasticsearch Repositories	
	32.7. Cassandra	
	Connecting to Cassandra	
	Spring Data Cassandra Repositories	
	32.8. Couchbase	
	Connecting to Couchbase	
	Spring Data Couchbase Repositories	
	32.9. LDAP	
	Connecting to an LDAP Server	
	Spring Data LDAP Repositories	
	Embedded In-memory LDAP Server	
	32.10. InfluxDB	
	Connecting to InfluxDB	
33.	Caching	
	33.1. Supported Cache Providers	
	Generic	124
	JCache (JSR-107)	124
	EhCache 2.x	125
	Hazelcast	125
	Infinispan	125
	Couchbase	125
	Redis	126
	Caffeine	126
	Simple	
	None	
34	Messaging	
•	34.1. JMS	
	ActiveMQ Support	
	Artemis Support	
	Using a JNDI ConnectionFactory	
	Sending a Message	
	Receiving a Message	
	34.2. AMQP	
	RabbitMQ support	
	Sending a Message	
	Receiving a Message	
	34.3. Apache Kafka Support	
	Sending a Message	
	Receiving a Message	
	Additional Kafka Properties	134
35.	Calling REST Services with RestTemplate	136
	35.1. RestTemplate Customization	136
36.	Calling REST Services with WebClient	138
	36.1. WebClient Customization	138
37.	Validation	139

	Sending Email	
39.	Distributed Transactions with JTA	141
	39.1. Using an Atomikos Transaction Manager	141
	39.2. Using a Bitronix Transaction Manager	141
	39.3. Using a Narayana Transaction Manager	142
	39.4. Using a Java EE Managed Transaction Manager	142
	39.5. Mixing XA and Non-XA JMS Connections	142
	39.6. Supporting an Alternative Embedded Transaction Manager	143
40.	Hazelcast	144
41.	Quartz Scheduler	145
42.	Spring Integration	146
43.	Spring Session	147
44.	Monitoring and Management over JMX	148
45.	Testing	149
	45.1. Test Scope Dependencies	149
	45.2. Testing Spring Applications	149
	45.3. Testing Spring Boot Applications	149
	Detecting Test Configuration	150
	Excluding Test Configuration	151
	Working with Random Ports	
	Mocking and Spying Beans	152
	Auto-configured Tests	
	Auto-configured JSON Tests	
	Auto-configured Spring MVC Tests	
	Auto-configured Spring WebFlux Tests	
	Auto-configured Data JPA Tests	
	Auto-configured JDBC Tests	
	Auto-configured jOOQ Tests	
	Auto-configured Data MongoDB Tests	
	Auto-configured Data Neo4j Tests	
	Auto-configured Data Redis Tests	
	Auto-configured Data LDAP Tests	
	Auto-configured REST Clients	
	Auto-configured Spring REST Docs Tests	
	Auto-configured Spring REST Docs Tests with Mock MVC	
	Auto-configured Spring REST Docs Tests with REST Assured	
	User Configuration and Slicing	
	Using Spock to Test Spring Boot Applications	
	45.4. Test Utilities	
	ConfigFileApplicationContextInitializer	
	EnvironmentTestUtils	
	OutputCapture	
	TestRestTemplate

75.7. Change Configuration Depending on the Environment	
75.8. Discover Built-in Options for External Properties	
76. Embedded Web Servers	
76.1. Use Another Web Server	
76.2. Configure Jetty	
76.3. Add a Servlet, Filter, or Listener to an Application	
Add a Servlet, Filter, or Listener by Using a Spring Bean	
rida a corriet, ritter, or meterior by coming a opining board minimum minimum	

	Disable Registration of a Servlet or Filter	248
	Add Servlets, Filters, and Listeners by Using Classpath Scanning	249
	76.4. Change the HTTP Port	249
	76.5. Use a Random Unassigned HTTP Port	249
	76.6. Discover the HTTP Port at Runtime	249
	76.7. Configure SSL	250
	76.8. Configure HTTP/2	250
	HTTP/2 with Undertow	
	HTTP/2 with Tomcat	250
	76.9. Configure Access Logging	251
	76.10. Running Behind a Front-end Proxy Server	
	Customize Tomcat's Proxy Configuration	
	76.11. Configure Tomcat	
	76.12. Enable Multiple Connectors with Tomcat	
	76.13. Use Tomcat's LegacyCookieProcessor	
	76.14. Configure Undertow	
	76.15. Enable Multiple Listeners with Undertow	
	76.16. Create WebSocket Endpoints Using @ServerEndpoint	
	76.17. Enable HTTP Response Compression	
77.	Spring MVC	
	77.1. Write a JSON REST Service	
	77.2. Write an XML REST Service	
	77.3. Customize the Jackson ObjectMapper	
	77.4. Customize the @ResponseBody Rendering	
	77.5. Handling Multipart File Uploads	
	77.6. Switch Off the Spring MVC DispatcherServlet	
	77.7. Switch off the Default MVC Configuration	
	77.8. Customize ViewResolvers	
78.	HTTP Clients	
	78.1. Configure RestTemplate to Use a Proxy	
79.	Logging	
	79.1. Configure Logback for Logging	
	Configure Logback for File-only Output	
	79.2. Configure Log4j for Logging	
	Use YAML or JSON to Configure Log4j 2	
80.	Data Access	
	80.1. Configure a Custom DataSource	
	80.2. Configure Two DataSources	
	80.3. Use Spring Data Repositories	
	80.4. Separate @Entity Definitions from Spring Configuration	
	80.5. Configure JPA Properties	
	80.6. Configure Hibernate Naming Strategy	
	80.7. Use a Custom EntityManagerFactory	
	80.8. Use Two EntityManagers	
	80.9. Use a Traditional persistence.xml File	
	80.10. Use Spring Data JPA and Mongo Repositories	
	80.11. Expose Spring Data Repositories as REST Endpoint	
	80.12. Configure a Component that is Used by JPA	
	80.13. Configure jOOQ with Two DataSources	
81	Database Initialization	
\sim 1.	Databass Initialization	-14

	81.1. Initialize a Database Using JPA	272
	81.2. Initialize a Database Using Hibernate	272
	81.3. Initialize a Database	272
	81.4. Initialize a Spring Batch Database	273
	81.5. Use a Higher-level Database Migration Tool	273
	Execute Flyway Database Migrations on Startup	273
	Execute Liquibase Database Migrations on Startup	274
	82. Messaging	275
	82.1. Disable Transacted JMS Session	
	83. Batch Applications	276
	83.1. Execute Spring Batch Jobs on Startup	
	84. Actuator	
	84.1. Change the HTTP Port or Address of the Actuator Endpoints	
	84.2. Customize the 'whitelabel' Error Page	
	85. Security	
	85.1. Switch off the Spring Boot Security Configuration	
	85.2. Change the AuthenticationManager and Add User Accounts	
	85.3. Enable HTTPS When Running behind a Proxy Server	
	86. Hot Swapping	
	86.1. Reload Static Content	
	86.2. Reload Templates without Restarting the Container	
	Thymeleaf Templates	
	FreeMarker Templates	
	·	
	Groovy Templates	
	86.3. Fast Application Restarts	
	86.4. Reload Java Classes without Restarting the Container	
	87. Build	
	87.1. Generate Build Information	
	87.2. Generate Git Information	
	87.3. Customize Dependency Versions	
	87.4. Create an Executable JAR with Maven	
	87.5. Use a Spring Boot Application as a Dependency	
	87.6. Extract Specific Libraries When an Executable Jar Runs	
	87.7. Create a Non-executable JAR with Exclusions	
	87.8. Remote Debug a Spring Boot Application Started with Maven	
	87.9. Build an Executable Archive from Ant without Using spring-boot-antlib	
	88. Traditional Deployment	
	88.1. Create a Deployable War File	
	88.2. Create a Deployable War File for Older Servlet Containers	288
	88.3. Convert an Existing Application to Spring Boot	288
	88.4. Deploying a WAR to WebLogic	290
	88.5. Deploying a WAR in an Old (Servlet 2.5) Container	290

Part I. Spring Boot Documentation

This section provides a brief overview of Spring Boot reference documentation. It serves as a map fo the rest of the document.

1. About the Documentation

The Spring Boot reference guide is available as

- HTML
- PDF
- EPUB

The latest copy is available at docs.spring.io/spring-boot/docs/current/reference.

Copies of this document may be made for your own use and for distribution to others, provided that you do not charge any fee for such copies and further provided that each copy contains this Copyright Notice, whether distributed in print or electronically.

2. Getting Help

If you have trouble with Spring Boot, we would like to help.

- Try the <u>How-to documents</u>. They provide solutions to the most common questions.
- Learn the Spring basics. Spring Boot builds on many other Spring projects. Check the spring.io website for a wealth of reference documentation. If you are starting out with Spring, try one of the guides.
- Ask a question. We monitor <u>stackoverflow.com</u> for questions tagged with <u>spring-boot</u>.
- Report bugs with Spring Boot at github.com/spring-projects/spring-boot/issues.

Note

All of Spring Boot is open source, including the documentation. If you find problems with the docs or if you want to improve them, please <u>get involved</u>.

3. First Steps

If you are getting started with Spring Boot or 'Spring' in general, start with the following topics:

• From scratch: Overview | Requirements | Installation

• Tutorial: Part 1 | Part 2

• Running your example: Part 1 | Part 2

4. Working with Spring Boot

Ready to actually start using Spring Boot? We have you covered:

- Build systems: Maven | Gradle | Ant | Starters
- Best practices: <u>Code Structure</u> | <u>@Configuration</u> | <u>@EnableAutoConfiguration</u> | <u>Beans and Dependency Injection</u>
- Running your code IDE | Packaged | Maven | Gradle
- Packaging your app: <u>Production jars</u>
- Spring Boot CLI: Using the CLI

5. Learning about Spring Boot Features

Need more details about Spring Boot's core features? The following content is for you:

- Core Features: SpringApplication | External Configuration | Profiles | Logging
- Web Applications: MVC | Embedded Containers
- Working with data: SQL | NO-SQL
- Messaging: Overview | JMS
- Testing: Overview | Boot Applications | Utils
- Extending: Auto-configuration | @Conditions

6. Moving to Production

When you are ready to push your Spring Boot application to production, we have <u>some tricks</u> that you might like:

• Management endpoints: Overview | Customization

• Connection options: <u>HTTP | JMX</u>

• Monitoring: Metrics | Auditing | Tracing | Process

7. Advanced Topics

Finally, we have a few topics for more advanced users:

- Spring Boot Applications Deployment: Cloud Deployment | OS Service
- Build tool plugins: Maven | Gradle
- Appendix: Application Properties | Auto-configuration classes | Executable Jars

Part II. Getting Started

If you are getting started with Spring Boot, or "Spring" in general, start by reading this section. It answers the basic "what?", "how?" and "why?" questions. It includes an introduction to Spring Boot, along with installation instructions. We then walk you through building your first Spring Boot application, discussing some core principles as we go.

8. Introducing Spring Boot

Spring Boot makes it easy to create stand-alone, production-grade Spring-based Applications that you can run. We take an opinionated view of the Spring platform and third-party libraries, so that you can get started with minimum fuss. Most Spring Boot applications need very little Spring configuration.

You can use Spring Boot to create Java applications that can be started by using <code>java -jar</code> or more traditional war deployments. We also provide a command line tool that runs "spring scripts".

Our primary goals are:

- Provide a radically faster and widely accessible getting-started experience for all Spring development.
- Be opinionated out of the box but get out of the way quickly as requirements start to diverge from the defaults.
- Provide a range of non-functional features that are common to large classes of projects (such as embedded servers, security, metrics, health checks, and externalized configuration).
- Absolutely no code generation and no requirement for XML configuration.

9. System Requirements

Spring Boot 2.0.0.BUILD-SNAPSHOT requires <u>Java 8</u> and <u>Spring Framework 5.0.3.BUILD-SNAPSHOT</u> or above. Explicit build support is provided for Maven 3.2+ and Gradle 4.

9.1 Servlet Containers

Spring Boot supports the following embedded servlet containers:

Name	Servlet Version
Tomcat 8.5	3.1
Jetty 9.4	3.1
Undertow 1.3	3.1

You can also deploy Spring Boot applications to any Servlet 3.0+ compatible container.

10. Installing Spring Boot

Spring Boot can be used with "classic" Java development tools or installed as a command line tool. Either way, you need <u>Java SDK v1.8</u> or higher. Before you begin, you should check your current Java installation by using the following command:

```
$ java -version
```

If you are new to Java development or if you want to experiment with Spring Boot, you might want to try the <u>Spring Boot CLI</u> (Command Line Interface) first. Otherwise, read on for "classic" installation instructions.

10.1 Installation Instructions for the Java Developer

You can use Spring Boot in the same way as any standard Java library. To do so, include the appropriate <code>spring-boot-*.jar</code> files on your classpath. Spring Boot does not require any special tools integration, so you can use any IDE or text editor. Also, there is nothing special about a Spring Boot application, so you can run and debug a Spring Boot application as you would any other Java program.

Although you *could* copy Spring Boot jars, we generally recommend that you use a build tool that supports dependency management (such as Maven or Gradle).

Maven Installation

Spring Boot is compatible with Apache Maven 3.2 or above. If you do not already have Maven installed, you can follow the instructions at <u>maven.apache.org</u>.

Tip

On many operating systems, Maven can be installed with a package manager. If you use OSX Homebrew, try brew install maven. Ubuntu users can run sudo apt-get install maven. Windows users with Chocolatey can run choco install maven from an elevated (administrator) prompt.

Spring Boot dependencies use the org.springframework.boot groupId. Typically, your Maven POM file inherits from the spring-boot-starter-parent project and declares dependencies to one or more <u>"Starters"</u>. Spring Boot also provides an optional <u>Maven plugin</u> to create executable jars.

The following listing shows a typical pom.xml file:

```
<dependencies>
 <dependency>
   <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-web</artifactId>
 </dependency>
</dependencies>
<!-- Package as an executable iar -->
<build>
 <plugins>
  <plugin>
   <groupId>org.springframework.boot</groupId>
   <artifactId>spring-boot-maven-plugin</artifactId>
  </plugin>
  </plugins>
 </build>
<!-- Add Spring repositories -->
<!-- (you don't need this if you are using a .RELEASE version) -->
<repositories>
 <repository>
  <id>spring-snapshots</id>
  <url>http://repo.spring.io/snapshot</url>
  <snapshots><enabled>true</enabled></snapshots>
 </repository>
 <repository>
  <id>spring-milestones</id>
  <url>http://repo.spring.io/milestone</url>
 </repository>
 </repositories>
<pluginRepositories>
 <pluginRepository>
  <id>spring-snapshots</id>
  <url>http://repo.spring.io/snapshot</url>
 </pluginRepository>
 <pluginRepository>
  <id>spring-milestones</id>
  <url>http://repo.spring.io/milestone</url>
  </pluginRepository>
</pluginRepositories>
</project>
```

Tip

The spring-boot-starter-parent is a great way to use Spring Boot, but it might not be suitable all of the time. Sometimes you may need to inherit from a different parent POM, or you might not like our default settings. In those cases, see the section called "Using Spring Boot without the Parent POM" for an alternative solution that uses an import scope.

Gradle Installation

Spring Boot is compatible with Gradle 4. If you do not already have Gradle installed, you can follow the instructions at www.gradle.org/.

Spring Boot dependencies can be declared by using the org.springframework.boot group. Typically, your project declares dependencies to one or more <u>"Starters"</u>. Spring Boot provides a useful <u>Gradle plugin</u> that can be used to simplify dependency declarations and to create executable jars.

Gradle Wrapper

The Gradle Wrapper provides a nice way of "obtaining" Gradle when you need to build a project. It is a small script and library that you commit alongside your code to bootstrap the build process. See docs.gradle.org/4.2.1/userguide/gradle_wrapper.html for details.

The following example shows a typical build.gradle file:

```
buildscript {
repositories {
 jcenter()
 maven { url 'http://repo.spring.io/snapshot' }
 maven { url 'http://repo.spring.io/milestone' }
dependencies {
 classpath 'org.springframework.boot:spring-boot-gradle-plugin:2.0.0.BUILD-SNAPSHOT'
apply plugin: 'java'
apply plugin: 'org.springframework.boot'
apply plugin: 'io.spring.dependency-management'
baseName = 'myproject'
version = '0.0.1-SNAPSHOT'
repositories {
maven { url "http://repo.spring.io/snapshot" }
maven { url "http://repo.spring.io/milestone" }
dependencies {
compile("org.springframework.boot:spring-boot-starter-web")
testCompile("org.springframework.boot:spring-boot-starter-test")
```

10.2 Installing the Spring Boot CLI

The Spring Boot CLI (Command Line Interface) is a command line tool that you can use to quickly prototype with Spring. It lets you run <u>Groovy</u> scripts, which means that you have a familiar Java-like syntax without so much boilerplate code.

You do not need to use the CLI to work with Spring Boot, but it is definitely the quickest way to get a Spring application off the ground.

Manual Installation

You can download the Spring CLI distribution from the Spring software repository:

- spring-boot-cli-2.0.0.BUILD-SNAPSHOT-bin.zip
- spring-boot-cli-2.0.0.BUILD-SNAPSHOT-bin.tar.gz

Cutting edge <u>snapshot distributions</u> are also available.

Once downloaded, follow the INSTALL.txt instructions from the unpacked archive. In summary, there is a spring script (spring.bat for Windows) in a bin/ directory in the .zip file. Alternatively, you can use java -jar with the .jar file (the script helps you to be sure that the classpath is set correctly).

Installation with SDKMAN!

SDKMAN! (The Software Development Kit Manager) can be used for managing multiple versions of various binary SDKs, including Groovy and the Spring Boot CLI. Get SDKMAN! from <u>sdkman.io</u> and install Spring Boot by using the following commands:

```
$ sdk install springboot
$ spring --version
Spring Boot v2.0.0.BUILD-SNAPSHOT
```

If you develop features for the CLI and want easy access to the version you built, use the following commands:

```
$ sdk install springboot dev /path/to/spring-boot/spring-boot-cli/target/spring-boot-cli-2.0.0.BUILD-
SNAPSHOT-bin/spring-2.0.0.BUILD-SNAPSHOT/
$ sdk default springboot dev
$ spring --version
Spring CLI v2.0.0.BUILD-SNAPSHOT
```

The preceding instructions install a local instance of spring called the dev instance. It points at your target build location, so every time you rebuild Spring Boot, spring is up-to-date.

You can see it by running the following command:

OSX Homebrew Installation

If you are on a Mac and use <u>Homebrew</u>, you can install the Spring Boot CLI by using the following commands:

```
$ brew tap pivotal/tap
$ brew install springboot
```

Homebrew installs spring to /usr/local/bin.

Note

If you do not see the formula, your installation of brew might be out-of-date. In that case, run brew update and try again.

MacPorts Installation

If you are on a Mac and use <u>MacPorts</u>, you can install the Spring Boot CLI by using the following command:

```
$ sudo port install spring-boot-cli
```

Command-line Completion

The Spring Boot CLI includes scripts that provide command completion for the <u>BASH</u> and <u>zsh</u> shells. You can source the script (also named spring) in any shell or put it in your personal or system-wide bash completion initialization. On a Debian system, the system-wide scripts are in /shell-completion/

bash and all scripts in that directory are executed when a new shell starts. For example, to run the script manually if you have installed by using SDKMAN!, use the following commands:

```
$ . ~/.sdkman/candidates/springboot/current/shell-completion/bash/spring
$ spring <HIT TAB HERE>
grab help jar run test version
```

Note

If you install the Spring Boot CLI by using Homebrew or MacPorts, the command-line completion scripts are automatically registered with your shell.

Quick-start Spring CLI Example

You can use the following web application to test your installation. To start, create a file called app.groovy, as follows:

```
@RestController
class ThisWillActuallyRun {

    @RequestMapping("/")
    String home() {
        "Hello World!"
    }
}
```

Then run it from a shell, as follows:

```
$ spring run app.groovy
```

Note

The first run of your application is slow, as dependencies are downloaded. Subsequent runs are much quicker.

Open <u>localhost:8080</u> in your favorite web browser. You should see the following output:

```
Hello World!
```

10.3 Upgrading from an Earlier Version of Spring Boot

If you are upgrading from an earlier release of Spring Boot, check the "migration guide" on the project wiki that provides detailed upgrade instructions. Check also the "release notes" for a list of "new and noteworthy" features for each release.

To upgrade an existing CLI installation, use the appropriate package manager command (for example, brew upgrade) or, if you manually installed the CLI, follow the <u>standard instructions</u>, remembering to update your PATH environment variable to remove any older references.

11. Developing Your First Spring Boot Application

This section describes how to develop a simple "Hello World!" web application that highlights some of Spring Boot's key features. We use Maven to build this project, since most IDEs support it.

Tip

The <u>spring.io</u> web site contains many "Getting Started" <u>guides</u> that use Spring Boot. If you need to solve a specific problem, check there first.

You can shortcut the steps below by going to <u>start.spring.io</u> and choosing the "Web" starter from the dependencies searcher. Doing so generates a new project structure so that you can <u>start coding right away</u>. Check the <u>Spring Initializr documentation</u> for more details.

Before we begin, open a terminal and run the following commands to ensure that you have valid versions of Java and Mayen installed:

```
$ java -version
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)

$ mvn -v
Apache Maven 3.3.9 (bb52d8502b132ec0a5a3f4c09453c07478323dc5; 2015-11-10T16:41:47+00:00)
Maven home: /usr/local/Cellar/maven/3.3.9/libexec
Java version: 1.8.0_102, vendor: Oracle Corporation
```

Note

This sample needs to be created in its own folder. Subsequent instructions assume that you have created a suitable folder and that it is your current directory.

11.1 Creating the POM

We need to start by creating a Maven pom.xml file. The pom.xml is the recipe that is used to build your project. Open your favorite text editor and add the following:

```
<?xml version="1.0" encoding="UTF-8"?>
xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
<modelVersion>4.0.0</modelVersion>
<groupId>com.example</groupId>
<artifactId>myproject</artifactId>
<version>0.0.1-SNAPSHOT
 <groupId>org.springframework.boot</groupId>
 <artifactId>spring-boot-starter-parent</artifactId>
 <version>2.0.0.BUILD-SNAPSHOT
<!-- Additional lines to be added here... -->
<!-- (you don't need this if you are using a .RELEASE version) -->
<repositories>
 <repository>
  <id>spring-snapshots</id>
 <url>http://repo.spring.io/snapshot</url>
```

```
<snapshots><enabled>true</enabled></snapshots>
  </repository>
  <repository>
  <id>spring-milestones</id>
  <url>http://repo.spring.io/milestone</url>
 </repository>
 </repositories>
<pluginRepositories>
 <pluginRepository>
  <id>spring-snapshots</id>
  <url>http://repo.spring.io/snapshot</url>
  </pluginRepository>
 <pluginRepository>
  <id>spring-milestones</id>
   <url>http://repo.spring.io/milestone</url>
  </pluginRepository>
</pluginRepositories>
</project>
```

The preceding listing should give you a working build. You can test it by running mvn package (for now, you can ignore the "jar will be empty - no content was marked for inclusion!" warning).

Note

At this point, you could import the project into an IDE (most modern Java IDEs include built-in support for Maven). For simplicity, we continue to use a plain text editor for this example.

11.2 Adding Classpath Dependencies

Spring Boot provides a number of "Starters" that let you add jars to your classpath. Our sample application has already used spring-boot-starter-parent in the parent section of the POM. The spring-boot-starter-parent is a special starter that provides useful Maven defaults. It also provides a <u>dependency-management</u> section so that you can omit version tags for "blessed" dependencies.

Other "Starters" provide dependencies that you are likely to need when developing a specific type of application. Since we are developing a web application, we add a spring-boot-starter-web dependency. Before that, we can look at what we currently have by running the following command:

```
$ mvn dependency:tree
[INFO] com.example:myproject:jar:0.0.1-SNAPSHOT
```

The mvn dependency: tree command prints a tree representation of your project dependencies. You can see that spring-boot-starter-parent provides no dependencies by itself. To add the necessary dependencies, edit your pom.xml and add the spring-boot-starter-web dependency immediately below the parent section:

```
<dependencies>
  <dependency>
   <groupId>org.springframework.boot</groupId>
   <artifactId>spring-boot-starter-web</artifactId>
  </dependency>
  </dependencies>
```

If you run mvn dependency: tree again, you see that there are now a number of additional dependencies, including the Tomcat web server and Spring Boot itself.

11.3 Writing the Code

To finish our application, we need to create a single Java file. By default, Maven compiles sources from src/main/java, so you need to create that folder structure and then add a file named src/main/java/Example.java to contain the following code:

```
import org.springframework.boot.*;
import org.springframework.boot.autoconfigure.*;
import org.springframework.web.bind.annotation.*;

@RestController
@EnableAutoConfiguration
public class Example {

    @RequestMapping("/")
    String home() {
    return "Hello World!";
    }

public static void main(String[] args) throws Exception {
        SpringApplication.run(Example.class, args);
    }
}
```

Although there is not much code here, quite a lot is going on. We step through the important parts in the next few sections.

The @RestController and @RequestMapping Annotations

The first annotation on our Example class is @RestController. This is known as a *stereotype* annotation. It provides hints for people reading the code and for Spring that the class plays a specific role. In this case, our class is a web @Controller, so Spring considers it when handling incoming web requests.

The <code>@RequestMapping</code> annotation provides "routing" information. It tells Spring that any HTTP request with the <code>/</code> path should be mapped to the <code>home</code> method. The <code>@RestController</code> annotation tells Spring to render the resulting string directly back to the caller.

Tip

The @RestController and @RequestMapping annotations are Spring MVC annotations. (They are not specific to Spring Boot.) See the MVC section in the Spring Reference Documentation for more details.

The @EnableAutoConfiguration Annotation

The second class-level annotation is <code>@EnableAutoConfiguration</code>. This annotation tells Spring Boot to "guess" how you want to configure Spring, based on the jar dependencies that you have added. Since <code>spring-boot-starter-web</code> added Tomcat and Spring MVC, the auto-configuration assumes that you are developing a web application and sets up Spring accordingly.

Starters and Auto-Configuration

Auto-configuration is designed to work well with "Starters", but the two concepts are not directly tied. You are free to pick and choose jar dependencies outside of the starters. Spring Boot still does its best to auto-configure your application.

The "main" Method

The final part of our application is the main method. This is just a standard method that follows the Java convention for an application entry point. Our main method delegates to Spring Boot's SpringApplication class by calling run. SpringApplication bootstraps our application, starting Spring, which, in turn, starts the auto-configured Tomcat web server. We need to pass Example.class as an argument to the run method to tell SpringApplication which is the primary Spring component. The args array is also passed through to expose any command-line arguments.

11.4 Running the Example

At this point, your application should work. Since you used the spring-boot-starter-parent POM, you have a useful run goal that you can use to start the application. Type mvn spring-boot:run from the root project directory to start the application. You should see output similar to the following:

If you open a web browser to localhost:8080, you should see the following output:

```
Hello World!
```

To gracefully exit the application, press ctrl-c.

11.5 Creating an Executable Jar

We finish our example by creating a completely self-contained executable jar file that we could run in production. Executable jars (sometimes called "fat jars") are archives containing your compiled classes along with all of the jar dependencies that your code needs to run.

Executable jars and Java

Java does not provide a standard way to load nested jar files (jar files that are themselves contained within a jar). This can be problematic if you are looking to distribute a self-contained application.

To solve this problem, many developers use "uber" jars. An uber jar packages all the classes from all the application's dependencies into a single archive. The problem with this approach is that it becomes hard to see which libraries are in your application. It can also be problematic if the same filename is used (but with different content) in multiple jars.

Spring Boot takes a different approach and lets you actually nest jars directly.

To create an executable jar, we need to add the spring-boot-maven-plugin to our pom.xml. To do so, insert the following lines just below the dependencies section:

```
<build>
  <plugins>
  <plugin>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-maven-plugin</artifactId>
    </plugin>
  </plugins>
</build>
```

Note

The spring-boot-starter-parent POM includes <executions> configuration to bind the repackage goal. If you do not use the parent POM, you need to declare this configuration yourself. See the <u>plugin documentation</u> for details.

Save your pom.xml and run mvn package from the command line, as follows:

If you look in the target directory, you should see myproject-0.0.1-SNAPSHOT.jar. The file should be around 10 MB in size. If you want to peek inside, you can use jar tvf, as follows:

```
$ jar tvf target/myproject-0.0.1-SNAPSHOT.jar
```

You should also see a much smaller file named myproject-0.0.1-SNAPSHOT.jar.original in the target directory. This is the original jar file that Maven created before it was repackaged by Spring Boot.

To run that application, use the java -jar command, as follows:

As before, to exit the application, press ctrl-c.

12. What to Read Next

Hopefully, this section provided some of the Spring Boot basics and got you on your way to writing your own applications. If you are a task-oriented type of developer, you might want to jump over to spring.io and check out some of the getting_started guides that solve specific "How do I do that with Spring?" problems. We also have Spring Boot-specific "How-to" reference documentation.

The <u>Spring Boot repository</u> also has a <u>bunch of samples</u> you can run. The samples are independent of the rest of the code (that is, you do not need to build the rest to run or use the samples).

Otherwise, the next logical step is to read <u>Part III, "Using Spring Boot"</u>. If you are really impatient, you could also jump ahead and read about <u>Spring Boot features</u>.

Part III. Using Spring Boot

This section goes into more detail about how you should use Spring Boot. It covers topics such as build systems, auto-configuration, and how to run your applications. We also cover some Spring Boot best practices. Although there is nothing particularly special about Spring Boot (it is just another library that you can consume), there are a few recommendations that, when followed, make your development process a little easier.

If you are starting out with Spring Boot, you should probably read the <u>Getting Started</u> guide before diving into this section.

13. Build Systems

It is strongly recommended that you choose a build system that supports <u>dependency management</u> and that can consume artifacts published to the "Maven Central" repository. We would recommend that you choose Maven or Gradle. It is possible to get Spring Boot to work with other build systems (Ant, for example), but they are not particularly well supported.

13.1 Dependency Management

Each release of Spring Boot provides a curated list of dependencies that it supports. In practice, you do not need to provide a version for any of these dependencies in your build configuration, as Spring Boot manages that for you. When you upgrade Spring Boot itself, these dependencies are upgraded as well in a consistent way.

Note

You can still specify a version and override Spring Boot's recommendations if you need to do so.

The curated list contains all the spring modules that you can use with Spring Boot as well as a refined list of third party libraries. The list is available as a standard <u>Bills of Materials (spring-boot-dependencies)</u> that can be used with both <u>Maven</u> and <u>Gradle</u>.

Warning

Each release of Spring Boot is associated with a base version of the Spring Framework. We **highly** recommend that you not specify its version.

13.2 Mayen

Maven users can inherit from the spring-boot-starter-parent project to obtain sensible defaults. The parent project provides the following features:

- Java 1.8 as the default compiler level.
- UTF-8 source encoding.
- A <u>Dependency Management section</u>, inherited from the spring-boot-dependencies pom, that
 manages the versions of common dependencies. This dependency management lets you omit

 version> tags for those dependencies when used in your own pom.
- Sensible <u>resource filtering</u>.
- Sensible plugin configuration (<u>exec plugin</u>, <u>Git commit ID</u>, and <u>shade</u>).
- Sensible resource filtering for application.properties and application.yml including profile-specific files (for example, application-dev.properties and application-dev.yml)

Note that, since the application.properties and application.yml files accept Spring style placeholders (\${...}), the Maven filtering is changed to use @..@ placeholders. (You can override that by setting a Maven property called resource.delimiter.)

Inheriting the Starter Parent

To configure your project to inherit from the spring-boot-starter-parent, set the parent as follows:

Note

You should need to specify only the Spring Boot version number on this dependency. If you import additional starters, you can safely omit the version number.

With that setup, you can also override individual dependencies by overriding a property in your own project. For instance, to upgrade to another Spring Data release train, you would add the following to your pom.xml:

Tip

Check the spring-boot-dependencies pom for a list of supported properties.

Using Spring Boot without the Parent POM

Not everyone likes inheriting from the spring-boot-starter-parent POM. You may have your own corporate standard parent that you need to use or you may prefer to explicitly declare all your Maven configuration.

If you do not want to use the <code>spring-boot-starter-parent</code>, you can still keep the benefit of the dependency management (but not the plugin management) by using a <code>scope=import</code> dependency, as follows:

The preceding sample setup does not let you override individual dependencies by using a property, as explained above. To achieve the same result, you need to add an entry in the dependencyManagement of your project before the spring-boot-dependencies entry. For instance, to upgrade to another Spring Data release train, you could add the following element to your pom.xml:

```
<dependencyManagement>
```

```
<dependencies>
 <!-- Override Spring Data release train provided by Spring Boot -->
  <groupId>org.springframework.data
  <artifactId>spring-data-releasetrain</artifactId>
  <version>Fowler-SR2</version>
  <scope>import</scope>
  <type>pom</type>
 </dependency>
 <dependency>
  <groupId>org.springframework.boot
  <artifactId>spring-boot-dependencies</artifactId>
  <version>2.0.0.BUILD-SNAPSHOT</version>
  <type>pom</type>
  <scope>import</scope>
 </dependency>
</dependencies>
</dependencyManagement>
```

Note

In the preceding example, we specify a *BOM*, but any dependency type can be overridden in the same way.

Using the Spring Boot Maven Plugin

Spring Boot includes a <u>Maven plugin</u> that can package the project as an executable jar. Add the plugin to your <plugins> section if you want to use it, as shown in the following example:

Note

If you use the Spring Boot starter parent pom, you need to add only the plugin. There is no need to configure it unless you want to change the settings defined in the parent.

13.3 Gradle

To learn about using Spring Boot with Gradle, please refer to the documentation for Spring Boot's Gradle plugin:

- · Reference (HTML and PDF)
- API

13.4 Ant

It is possible to build a Spring Boot project using Apache Ant+Ivy. The spring-boot-antlib "AntLib" module is also available to help Ant create executable jars.

To declare dependencies, a typical ivy.xml file looks something like the following example:

A typical build.xml looks like the following example:

```
oject
xmlns:ivy="antlib:org.apache.ivy.ant"
xmlns:spring-boot="antlib:org.springframework.boot.ant"
name="myapp" default="build">
cproperty name="spring-boot.version" value="2.0.0.BUILD-SNAPSHOT" />
<target name="resolve" description="--> retrieve dependencies with ivy">
 <ivy:retrieve pattern="lib/[conf]/[artifact]-[type]-[revision].[ext]" />
<target name="classpaths" depends="resolve">
 <path id="compile.classpath">
  <fileset dir="lib/compile" includes="*.jar" />
 </path>
</target>
<target name="init" depends="classpaths">
 <mkdir dir="build/classes" />
</target>
<target name="compile" depends="init" description="compile">
 <javac srcdir="src/main/java" destdir="build/classes" classpathref="compile.classpath" />
</target>
<target name="build" depends="compile">
 <spring-boot:exejar destfile="build/myapp.jar" classes="build/classes">
  <spring-boot:lib>
   <fileset dir="lib/runtime" />
  </spring-boot:lib>
 </spring-boot:exejar>
</target>
</project>
```

Tip

If you do not want to use the spring-boot-antlib module, see the <u>Section 87.9</u>, "Build an <u>Executable Archive from Ant without Using spring-boot-antlib"</u> "How-to".

13.5 Starters

Starters are a set of convenient dependency descriptors that you can include in your application. You get a one-stop shop for all the Spring and related technologies that you need without having to hunt through sample code and copy-paste loads of dependency descriptors. For example, if you want to get started using Spring and JPA for database access, include the <code>spring-boot-starter-data-jpa</code> dependency in your project.

The starters contain a lot of the dependencies that you need to get a project up and running quickly and with a consistent, supported set of managed transitive dependencies.

What's in a name

All **official** starters follow a similar naming pattern; <code>spring-boot-starter-*</code>, where * is a particular type of application. This naming structure is intended to help when you need to find a starter. The Maven integration in many IDEs lets you search dependencies by name. For example, with the appropriate Eclipse or STS plugin installed, you can press <code>ctrl-space</code> in the POM editor and type "spring-boot-starter" for a complete list.

As explained in the "<u>Creating Your Own Starter</u>" section, third party starters should not start with <code>spring-boot</code>, as it is reserved for official Spring Boot artifacts. Rather, a third-party starter typically starts with the name of the project. For example, a third-party starter project called <code>thirdpartyproject</code> would typically be named <code>thirdpartyproject-spring-boot-starter</code>.

The following application starters are provided by Spring Boot under the org.springframework.boot group:

Table 13.1. Spring Boot application starters

Name	Description	Pom
spring-boot-starter	Core starter, including auto- configuration support, logging and YAML	<u>Pom</u>
spring-boot-starter- activemq	Starter for JMS messaging using Apache ActiveMQ	Pom
spring-boot-starter- amqp	Starter for using Spring AMQP and Rabbit MQ	<u>Pom</u>
spring-boot-starter-aop	Starter for aspect-oriented programming with Spring AOP and AspectJ	<u>Pom</u>
spring-boot-starter- artemis	Starter for JMS messaging using Apache Artemis	Pom
spring-boot-starter- batch	Starter for using Spring Batch	Pom
spring-boot-starter-cache	Starter for using Spring Framework's caching support	Pom
spring-boot-starter- cloud-connectors	Starter for using Spring Cloud Connectors which simplifies connecting to services in cloud platforms like Cloud Foundry and Heroku	Pom
spring-boot-starter- data-cassandra	Starter for using Cassandra distributed database and Spring Data Cassandra	Pom

Name	Description	Pom
spring-boot-starter- data-cassandra-reactive	Starter for using Cassandra distributed database and Spring Data Cassandra Reactive	Pom
spring-boot-starter- data-couchbase	Starter for using Couchbase document-oriented database and Spring Data Couchbase	Pom
spring-boot-starter- data-couchbase-reactive	Starter for using Couchbase document-oriented database and Spring Data Couchbase Reactive	Pom
spring-boot-starter-data-elasticsearch	Starter for using Elasticsearch search and analytics engine and Spring Data Elasticsearch	Pom
spring-boot-starter-data-jpa	Starter for using Spring Data JPA with Hibernate	Pom
spring-boot-starter- data-ldap	Starter for using Spring Data LDAP	Pom
spring-boot-starter- data-mongodb	Starter for using MongoDB document-oriented database and Spring Data MongoDB	Pom
spring-boot-starter-data-mongodb-reactive	Starter for using MongoDB document-oriented database and Spring Data MongoDB Reactive	Pom
spring-boot-starter- data-neo4j	Starter for using Neo4j graph database and Spring Data Neo4j	Pom
spring-boot-starter- data-redis	Starter for using Redis key- value data store with Spring Data Redis and the Lettuce client	Pom
spring-boot-starter-data-redis-reactive	Starter for using Redis key- value data store with Spring Data Redis reactive and the Lettuce client	Pom
spring-boot-starter- data-rest	Starter for exposing Spring Data repositories over REST using Spring Data REST	Pom

Name	Description	Pom
spring-boot-starter-data-solr	Starter for using the Apache Solr search platform with Spring Data Solr	Pom
spring-boot-starter- freemarker	Starter for building MVC web applications using FreeMarker views	Pom
spring-boot-starter- groovy-templates	Starter for building MVC web applications using Groovy Templates views	Pom
spring-boot-starter- hateoas	Starter for building hypermedia- based RESTful web application with Spring MVC and Spring HATEOAS	Pom
spring-boot-starter- integration	Starter for using Spring Integration	Pom
spring-boot-starter- jdbc	Starter for using JDBC with the Tomcat JDBC connection pool	Pom
spring-boot-starter- jersey	Starter for building RESTful web applications using JAX-RS and Jersey. An alternative to spring-boot-starter-web	Pom
spring-boot-starter- jooq	Starter for using jOOQ to access SQL databases. An alternative to spring-boot-starter-data-jpa Or spring-boot-starter-jdbc	Pom
spring-boot-starter- json	Starter for reading and writing json	Pom
spring-boot-starter- jta-atomikos	Starter for JTA transactions using Atomikos	Pom
spring-boot-starter- jta-bitronix	Starter for JTA transactions using Bitronix	Pom
spring-boot-starter- jta-narayana	Spring Boot Narayana JTA Starter	Pom
spring-boot-starter- mail	Starter for using Java Mail and Spring Framework's email sending support	Pom

Name	Description	Pom
spring-boot-starter- mustache	Starter for building web applications using Mustache views	<u>Pom</u>
spring-boot-starter- quartz	Spring Boot Quartz Starter	Pom
spring-boot-starter- security	Starter for using Spring Security	<u>Pom</u>
spring-boot-starter- test	Starter for testing Spring Boot applications with libraries including JUnit, Hamcrest and Mockito	Pom
spring-boot-starter- thymeleaf	Starter for building MVC web applications using Thymeleaf views	Pom
spring-boot-starter- validation	Starter for using Java Bean Validation with Hibernate Validator	Pom
spring-boot-starter-web	Starter for building web, including RESTful, applications using Spring MVC. Uses Tomcat as the default embedded container	Pom
spring-boot-starter- web-services	Starter for using Spring Web Services	Pom
spring-boot-starter- webflux	Starter for building WebFlux applications using Spring Framework's Reactive Web support	Pom
spring-boot-starter- websocket	Starter for building WebSocket applications using Spring Framework's WebSocket support	Pom

In addition to the application starters, the following starters can be used to add $\underline{\textit{production ready}}$ features:

Table 13.2. Spring Boot production starters

Name	Description	Pom
spring-boot-starter- actuator	Starter for using Spring Boot's Actuator which provides production ready features to help you monitor and manage your application	Pom

Finally, Spring Boot also includes the following starters that can be used if you want to exclude or swap specific technical facets:

Table 13.3. Spring Boot technical starters

Name	Description	Pom
spring-boot-starter- jetty	Starter for using Jetty as the embedded servlet container. An alternative to <pre>spring-boot-</pre>	Pom
spring-boot-starter-log4j2	Starter for using Log4j2 for logging. An alternative to spring-boot-starter-logging	Pom
spring-boot-starter- logging	Starter for logging using Logback. Default logging starter	Pom
spring-boot-starter- reactor-netty	Starter for using Reactor Netty as the embedded reactive HTTP server.	Pom
spring-boot-starter- tomcat	Starter for using Tomcat as the embedded servlet container. Default servlet container starter used by spring-boot-starter-web	Pom
spring-boot-starter- undertow	Starter for using Undertow as the embedded servlet container. An alternative to spring-boot-starter-tomcat	Pom

Tip

For a list of additional community contributed starters, see the $\underline{\sf README}$ file in the $\underline{\sf spring-bootstarters}$ module on GitHub.

14. Structuring Your Code

Spring Boot does not require any specific code layout to work. However, there are some best practices that help.

14.1 Using the "default" Package

When a class does not include a package declaration, it is considered to be in the "default package". The use of the "default package" is generally discouraged and should be avoided. It can cause particular problems for Spring Boot applications that use the @ComponentScan, @EntityScan, or @SpringBootApplication annotations, since every class from every jar is read.

Tip

We recommend that you follow Java's recommended package naming conventions and use a reversed domain name (for example, com.example.project).

14.2 Locating the Main Application Class

We generally recommend that you locate your main application class in a root package above other classes. The <code>@EnableAutoConfiguration</code> annotation is often placed on your main class, and it implicitly defines a base "search package" for certain items. For example, if you are writing a JPA application, the package of the <code>@EnableAutoConfiguration</code> annotated class is used to search for <code>@Entity</code> items.

Using a root package also lets the <code>@ComponentScan</code> annotation be used without needing to specify a <code>basePackage</code> attribute. You can also use the <code>@SpringBootApplication</code> annotation if your main class is in the root package.

The following listing shows a typical layout:

```
com
+- example
+- myapplication
+- Application.java
|
+- customer
| +- Customer.java
| +- CustomerController.java
| +- CustomerService.java
| +- CustomerRepository.java
| +- Order
+- Order
+- Order
+- Order.java
+- OrderController.java
+- OrderService.java
+- OrderRepository.java
```

The Application. java file would declare the main method, along with the basic @Configuration, as follows:

```
package com.example.myapplication;
import org.springframework.boot.SpringApplication;
import org.springframework.boot.autoconfigure.EnableAutoConfiguration;
import org.springframework.context.annotation.ComponentScan;
import org.springframework.context.annotation.Configuration;
```

```
@Configuration
@EnableAutoConfiguration
@ComponentScan
public class Application {

public static void main(String[] args) {
    SpringApplication.run(Application.class, args);
  }
}
```

15. Configuration Classes

Spring Boot favors Java-based configuration. Although it is possible to use SpringApplication with XML sources, we generally recommend that your primary source be a single @Configuration class. Usually the class that defines the main method is a good candidate as the primary @Configuration.

Tip

Many Spring configuration examples have been published on the Internet that use XML configuration. If possible, always try to use the equivalent Java-based configuration. Searching for Enable* annotations can be a good starting point.

15.1 Importing Additional Configuration Classes

You need not put all your @Configuration into a single class. The @Import annotation can be used to import additional configuration classes. Alternatively, you can use @ComponentScan to automatically pick up all Spring components, including @Configuration classes.

15.2 Importing XML Configuration

If you absolutely must use XML based configuration, we recommend that you still start with a @Configuration class. You can then use an @ImportResource annotation to load XML configuration files.

16. Auto-configuration

Spring Boot auto-configuration attempts to automatically configure your Spring application based on the jar dependencies that you have added. For example, if HSQLDB is on your classpath, and you have not manually configured any database connection beans, then Spring Boot auto-configures an in-memory database.

You need to opt-in to auto-configuration by adding the @EnableAutoConfiguration or @SpringBootApplication annotations to one of your @Configuration classes.

Tip

You should only ever add one <code>@EnableAutoConfiguration</code> annotation. We generally recommend that you add it to your primary <code>@Configuration</code> class.

16.1 Gradually Replacing Auto-configuration

Auto-configuration is non-invasive. At any point, you can start to define your own configuration to replace specific parts of the auto-configuration. For example, if you add your own DataSource bean, the default embedded database support backs away.

If you need to find out what auto-configuration is currently being applied, and why, start your application with the --debug switch. Doing so enables debug logs for a selection of core loggers and logs a conditions report to the console.

16.2 Disabling Specific Auto-configuration Classes

If you find that specific auto-configuration classes that you do not want are being applied, you can use the exclude attribute of @EnableAutoConfiguration to disable them, as shown in the following example:

```
import org.springframework.boot.autoconfigure.*;
import org.springframework.boot.autoconfigure.jdbc.*;
import org.springframework.context.annotation.*;

@Configuration
@EnableAutoConfiguration(exclude={DataSourceAutoConfiguration.class})
public class MyConfiguration {
}
```

If the class is not on the classpath, you can use the <code>excludeName</code> attribute of the annotation and specify the fully qualified name instead. Finally, you can also control the list of auto-configuration classes to exclude by using the <code>spring.autoconfigure.exclude</code> property.

Tip

You can define exclusions both at the annotation level and by using the property.

17. Spring Beans and Dependency Injection

You are free to use any of the standard Spring Framework techniques to define your beans and their injected dependencies. For simplicity, we often find that using @ComponentScan (to find your beans) and using @Autowired (to do constructor injection) works well.

If you structure your code as suggested above (locating your application class in a root package), you can add @ComponentScan without any arguments. All of your application components (@Component, @Service, @Repository, @Controller etc.) are automatically registered as Spring Beans.

The following example shows a @Service Bean that uses constructor injection to obtain a required RiskAssessor bean:

```
package com.example.service;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.stereotype.Service;

@Service
public class DatabaseAccountService implements AccountService {
    private final RiskAssessor riskAssessor;
    @Autowired
    public DatabaseAccountService(RiskAssessor riskAssessor) {
        this.riskAssessor = riskAssessor;
    }

// ...
}
```

If a bean has one constructor, you can omit the @Autowired, as shown in the following example:

```
@Service
public class DatabaseAccountService implements AccountService {
   private final RiskAssessor riskAssessor;
   public DatabaseAccountService(RiskAssessor riskAssessor) {
     this.riskAssessor = riskAssessor;
   }
   // ...
}
```

Tip

Notice how using constructor injection lets the riskAssessor field be marked as final, indicating that it cannot be subsequently changed.

18. Using the @SpringBootApplication Annotation

Many Spring Boot developers always have their main class annotated with @Configuration, @EnableAutoConfiguration, and @ComponentScan. Since these annotations are so frequently used together (especially if you follow the <u>best practices</u> above), Spring Boot provides a convenient @SpringBootApplication alternative.

The @SpringBootApplication annotation is equivalent to using @Configuration, @EnableAutoConfiguration, and @ComponentScan with their default attributes, as shown in the following example:

```
package com.example.myapplication;
import org.springframework.boot.SpringApplication;
import org.springframework.boot.autoconfigure.SpringBootApplication;

@SpringBootApplication // same as @Configuration @EnableAutoConfiguration @ComponentScan
public class Application {

public static void main(String[] args) {
    SpringApplication.run(Application.class, args);
    }
}
```

Note

@SpringBootApplication also provides aliases to customize the attributes of @EnableAutoConfiguration and @ComponentScan.

19. Running Your Application

One of the biggest advantages of packaging your application as a jar and using an embedded HTTP server is that you can run your application as you would any other. Debugging Spring Boot applications is also easy. You do not need any special IDE plugins or extensions.

Note

This section only covers jar based packaging. If you choose to package your application as a war file, you should refer to your server and IDE documentation.

19.1 Running from an IDE

You can run a Spring Boot application from your IDE as a simple Java application. However, you first need to import your project. Import steps vary depending on your IDE and build system. Most IDEs can import Maven projects directly. For example, Eclipse users can select $\mathtt{Import...} \rightarrow \mathtt{Existing}$ Maven $\mathtt{Projects}$ from the File menu.

If you cannot directly import your project into your IDE, you may be able to generate IDE metadata by using a build plugin. Maven includes plugins for <u>Eclipse</u> and <u>IDEA</u>. Gradle offers plugins for <u>various IDEs</u>.

Tip

If you accidentally run a web application twice, you see a "Port already in use" error. STS users can use the Relaunch button rather than the Run button to ensure that any existing instance is closed.

19.2 Running as a Packaged Application

If you use the Spring Boot Maven or Gradle plugins to create an executable jar, you can run your application using java -jar, as shown in the following example:

```
$ java -jar target/myapplication-0.0.1-SNAPSHOT.jar
```

It is also possible to run a packaged application with remote debugging support enabled. Doing so lets you attach a debugger to your packaged application, as shown in the following example:

```
$ java -Xdebug -Xrunjdwp:server=y,transport=dt_socket,address=8000,suspend=n \
    -jar target/myapplication-0.0.1-SNAPSHOT.jar
```

19.3 Using the Maven Plugin

The Spring Boot Maven plugin includes a run goal that can be used to quickly compile and run your application. Applications run in an exploded form, as they do in your IDE. The following example shows a typical Maven command to run a Spring Boot application:

```
$ mvn spring-boot:run
```

You might also want to use the MAVEN_OPTS operating system environment variable, as shown in the following example:

```
$ export MAVEN_OPTS=-Xmx1024m
```

19.4 Using the Gradle Plugin

The Spring Boot Gradle plugin also includes a bootRun task that can be used to run your application in an exploded form. The bootRun task is added whenever you apply the org.springframework.boot and java plugins and is shown in the following example:

```
$ gradle bootRun
```

You might also want to use the JAVA_OPTS operating system environment variable, as shown in the following example:

```
$ export JAVA_OPTS=-Xmx1024m
```

19.5 Hot Swapping

Since Spring Boot applications are just plain Java applications, JVM hot-swapping should work out of the box. JVM hot swapping is somewhat limited with the bytecode that it can replace. For a more complete solution, <u>JRebel</u> can be used.

The spring-boot-devtools module also includes support for quick application restarts. See the <u>Chapter 20, Developer Tools</u> section later in this chapter and the <u>Hot swapping "How-to"</u> for details.

20. Developer Tools

Spring Boot includes an additional set of tools that can make the application development experience a little more pleasant. The <code>spring-boot-devtools</code> module can be included in any project to provide additional development-time features. To include devtools support, add the module dependency to your build, as shown in the following listings for Maven and Gradle:

Maven.

```
<dependencies>
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-devtools</artifactId>
<optional>true</optional>
</dependency>
</dependencies>
```

Gradle.

```
dependencies {
  compile("org.springframework.boot:spring-boot-devtools")
}
```

Note

Developer tools are automatically disabled when running a fully packaged application. If your application is launched from <code>java -jar</code> or if it is started from a special classloader, then it is considered a "production application". Flagging the dependency as optional is a best practice that prevents devtools from being transitively applied to other modules that use your project. Gradle does not support <code>optional</code> dependencies out-of-the-box, so you may want to have a look at the <code>propdeps-plugin</code>.

Tip

Repackaged archives do not contain devtools by default. If you want to use a <u>certain remote</u> <u>devtools feature</u>, you need to disable the <u>excludeDevtools</u> build property to include it. The property is supported with both the Maven and Gradle plugins.

20.1 Property Defaults

Several of the libraries supported by Spring Boot use caches to improve performance. For example, template engines cache compiled templates to avoid repeatedly parsing template files. Also, Spring MVC can add HTTP caching headers to responses when serving static resources.

While caching is very beneficial in production, it can be counter-productive during development, preventing you from seeing the changes you just made in your application. For this reason, spring-boot-devtools disables the caching options by default.

Cache options are usually configured by settings in your application.properties file. For example, Thymeleaf offers the spring.thymeleaf.cache property. Rather than needing to set these properties manually, the spring-boot-devtools module automatically applies sensible development-time configuration.

Tip

For a complete list of the properties that are applied by the devtools, see DevToolsPropertyDefaultsPostProcessor.

20.2 Automatic Restart

Applications that use <code>spring-boot-devtools</code> automatically restart whenever files on the classpath change. This can be a useful feature when working in an IDE, as it gives a very fast feedback loop for code changes. By default, any entry on the classpath that points to a folder is monitored for changes. Note that certain resources, such as static assets and view templates, <u>do not need to restart the application</u>.

Triggering a restart

As DevTools monitors classpath resources, the only way to trigger a restart is to update the classpath. The way in which you cause the classpath to be updated depends on the IDE that you are using. In Eclipse, saving a modified file causes the classpath to be updated and triggers a restart. In IntelliJ IDEA, building the project (Build -> Make Project) has the same effect.

Note

As long as forking is enabled, you can also start your application by using the supported build plugins (Maven and Gradle), since DevTools needs an isolated application classloader to operate properly. By default, Gradle and Maven do that when they detect DevTools on the classpath.

Tip

Automatic restart works very well when used with LiveReload. <u>See the LiveReload section</u> for details. If you use JRebel, automatic restarts are disabled in favor of dynamic class reloading. Other devtools features (such as LiveReload and property overrides) can still be used.

Note

DevTools relies on the application context's shutdown hook to close it during a restart. It does not work correctly if you have disabled the shutdown hook (SpringApplication.setRegisterShutdownHook(false)).

Note

When deciding if an entry on the classpath should trigger a restart when it changes, DevTools automatically ignores projects named spring-boot, spring-boot-devtools, spring-boot-autoconfigure, spring-boot-actuator, and spring-boot-starter.

Note

DevTools needs to customize the ResourceLoader used by the ApplicationContext. If your application provides one already, it is going to be wrapped. Direct override of the getResource method on the ApplicationContext is not supported.

Restart vs Reload

The restart technology provided by Spring Boot works by using two classloaders. Classes that do not change (for example, those from third-party jars) are loaded into a *base* classloader. Classes that you are actively developing are loaded into a *restart* classloader. When the application is restarted, the *restart* classloader is thrown away and a new one is created. This approach means that application restarts are typically much faster than "cold starts", since the *base* classloader is already available and populated.

If you find that restarts are not quick enough for your applications or you encounter classloading issues, you could consider reloading technologies such as <u>JRebel</u> from ZeroTurnaround. These work by rewriting classes as they are loaded to make them more amenable to reloading.

Logging changes in condition evaluation

By default, each time your application restarts, a report showing the condition evaluation delta is logged. The report shows the changes to your application's auto-configuration as you make changes such as adding or removing beans and setting configuration properties.

To disable the logging of the report, set the following property:

spring.devtools.restart.log-condition-evaluation-delta=false

Excluding Resources

Certain resources do not necessarily need to trigger a restart when they are changed. For example, Thymeleaf templates can be edited in-place. By default, changing resources in /META-INF/maven, /META-INF/resources, /resources, /static, /public, or /templates does not trigger a restart but does trigger a live reload. If you want to customize these exclusions, you can use the spring.devtools.restart.exclude property. For example, to exclude only /static and /public you would set the following property:

 ${\tt spring.devtools.restart.exclude=static/**,public/**}$

Tip

If you want to keep those defaults and *add* additional exclusions, use the spring.devtools.restart.additional-exclude property instead.

Watching Additional Paths

You may want your application to be restarted or reloaded when you make changes to files that are not on the classpath. To do so, use the <code>spring.devtools.restart.additional-paths</code> property to configure additional paths to watch for changes. You can use the <code>spring.devtools.restart.exclude</code> property <code>described earlier</code> to control whether changes beneath the additional paths trigger a full restart or a <code>live reload</code>.

Disabling Restart

If you do not want to use the restart feature, you can disable it by using the spring.devtools.restart.enabled property. In most cases, you can set this property in your application.properties (doing so still initializes the restart classloader, but it does not watch for file changes).

If you need to *completely* disable restart support (for example, because it does not work with a specific library), you need to set the spring.devtools.restart.enabled System property to false before calling SpringApplication.run(...), as shown in the following example:

```
public static void main(String[] args) {
   System.setProperty("spring.devtools.restart.enabled", "false");
   SpringApplication.run(MyApp.class, args);
}
```

Using a Trigger File

If you work with an IDE that continuously compiles changed files, you might prefer to trigger restarts only at specific times. To do so, you can use a "trigger file", which is a special file that must be modified when you want to actually trigger a restart check. Changing the file only triggers the check and the restart only occurs if Devtools has detected it has to do something. The trigger file can be updated manually or with an IDE plugin.

To use a trigger file, set the spring.devtools.restart.trigger-file property to the path of your trigger file.

Tip

You might want to set spring.devtools.restart.trigger-file as a global setting, so that all your projects behave in the same way.

Customizing the Restart Classloader

As described earlier in the <u>Restart vs Reload</u> section, restart functionality is implemented by using two classloaders. For most applications, this approach works well. However, it can sometimes cause classloading issues.

By default, any open project in your IDE is loaded with the "restart" classloader, and any regular .jar file is loaded with the "base" classloader. If you work on a multi-module project, and not every module is imported into your IDE, you may need to customize things. To do so, you can create a META-INF/spring-devtools.properties file.

The spring-devtools.properties file can contain properties prefixed with restart.exclude and restart.include. The include elements are items that should be pulled up into the "restart" classloader, and the exclude elements are items that should be pushed down into the "base" classloader. The value of the property is a regex pattern that is applied to the classpath, as shown in the following example:

```
restart.exclude.companycommonlibs=/mycorp-common-[\\w-]+\.jar
restart.include.projectcommon=/mycorp-myproj-[\\w-]+\.jar
```

Note

All property keys must be unique. As long as a property starts with restart.include. or restart.exclude. it is considered.

Tip

All META-INF/spring-devtools.properties from the classpath are loaded. You can package files inside your project, or in the libraries that the project consumes.

Known Limitations

Restart functionality does not work well with objects that are deserialized by using standard ObjectInputStream. lf you need to deserialize data, you to use Spring's ConfigurableObjectInputStream in combination with Thread.currentThread().getContextClassLoader().

Unfortunately, several third-party libraries deserialize without considering the context classloader. If you find such a problem, you need to request a fix with the original authors.

20.3 LiveReload

The spring-boot-devtools module includes an embedded LiveReload server that can be used to trigger a browser refresh when a resource is changed. LiveReload browser extensions are freely available for Chrome, Firefox and Safari from <u>livereload.com</u>.

If you do not want to start the LiveReload server when your application runs, you can set the spring.devtools.livereload.enabled property to false.

Note

You can only run one LiveReload server at a time. Before starting your application, ensure that no other LiveReload servers are running. If you start multiple applications from your IDE, only the first has LiveReload support.

20.4 Global Settings

You can configure global devtools settings by adding a file named .spring-boot-devtools.properties to your \$HOME folder (note that the filename starts with "."). Any properties added to this file apply to *all* Spring Boot applications on your machine that use devtools. For example, to configure restart to always use a trigger file, you would add the following property:

~/.spring-boot-devtools.properties.

```
spring.devtools.reload.trigger-file=.reloadtrigger
```

20.5 Remote Applications

The Spring Boot developer tools are not limited to local development. You can also use several features when running applications remotely. Remote support is opt-in. To enable it, you need to make sure that devtools is included in the repackaged archive, as shown in the following listing:

```
<build>
<plugins>
<plugin>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
<configuration>
    <excludeDevtools>false</excludeDevtools>
    </configuration>
    </plugin>
</plugins>
</build>
```

Then you need to set a spring.devtools.remote.secret property, as shown in the following example:

spring.devtools.remote.secret=mysecret

Warning

Enabling spring-boot-devtools on a remote application is a security risk. You should never enable support on a production deployment.

Remote devtools support is provided in two parts: a server-side endpoint that accepts connections and a client application that you run in your IDE. The server component is automatically enabled when the <code>spring.devtools.remote.secret</code> property is set. The client component must be launched manually.

Running the Remote Client Application

The remote client application is designed to be run from within your IDE. You need to run org.springframework.boot.devtools.RemoteSpringApplication with the same classpath as the remote project that you connect to. The application's single required argument is the remote URL to which it connects.

For example, if you are using Eclipse or STS and you have a project named my-app that you have deployed to Cloud Foundry, you would do the following:

- Select Run Configurations... from the Run menu.
- Create a new Java Application "launch configuration".
- Browse for the my-app project.
- Use org.springframework.boot.devtools.RemoteSpringApplication as the main class.
- Add https://myapp.cfapps.io to the Program arguments (or whatever your remote URL is).

A running remote client might resemble the following listing:

```
/\\ / __
        .__|_| |_|_| |_\__, |
                                     |_|_\_
                                             __|_|_|_\_
 :: Spring Boot Remote :: 2.0.0.BUILD-SNAPSHOT

Started RemoteSpringApplication in 0.74 seconds (JVM running for 1.105)
```

Note

Because the remote client is using the same classpath as the real application it can directly read application properties. This is how the spring.devtools.remote.secret property is read and passed to the server for authentication.

Tip

It is always advisable to use https:// as the connection protocol, so that traffic is encrypted and passwords cannot be intercepted.

Tip

If you need to use a proxy to access the remote application, configure the spring.devtools.remote.proxy.host and spring.devtools.remote.proxy.port properties.

Remote Update

The remote client monitors your application classpath for changes in the same way as the <u>local restart</u>. Any updated resource is pushed to the remote application and (*if required*) triggers a restart. This can be helpful if you iterate on a feature that uses a cloud service that you do not have locally. Generally, remote updates and restarts are much quicker than a full rebuild and deploy cycle.

Note

Files are only monitored when the remote client is running. If you change a file before starting the remote client, it is not pushed to the remote server.

21. Packaging Your Application for Production

Executable jars can be used for production deployment. As they are self-contained, they are also ideally suited for cloud-based deployment.

For additional "production ready" features, such as health, auditing, and metric REST or JMX endpoints, consider adding spring-boot-actuator. See <u>Part V, "Spring Boot Actuator: Production-ready features"</u> for details.

22. What to Read Next

You should now understand how you can use Spring Boot and some best practices that you should follow. You can now go on to learn about specific <u>Spring Boot features</u> in depth, or you could skip ahead and read about the "<u>production ready</u>" aspects of Spring Boot.

Part IV. Spring Boot features

This section dives into the details of Spring Boot. Here you can learn about the key features that you may want to use and customize. If you have not already done so, you might want to read the "Part II, "Getting Started" and "Part III, "Using Spring Boot" sections, so that you have a good grounding of the basics.

23. SpringApplication

The SpringApplication class provides a convenient way to bootstrap a Spring application that is started from a main() method. In many situations, you can delegate to the static SpringApplication.run method, as shown in the following example:

```
public static void main(String[] args) {
   SpringApplication.run(MySpringConfiguration.class, args);
}
```

When your application starts, you should see something similar to the following output:

```
_ | '_ | '_| | '_ \/ _` | \ \ \ \
    ._|_| |_| |_\_, | / / / /
======|_|======|___/=/_/_/
:: Spring Boot :: v2.0.0.BUILD-SNAPSHOT
2013-07-31 00:08:16.117 INFO 56603 --- [
                                               main] o.s.b.s.app.SampleApplication
Starting SampleApplication v0.1.0 on mycomputer with PID 56603 (/apps/myapp.jar started by pwebb)
2013-07-31 00:08:16.166 INFO 56603 --- [
                                              mainl
ationConfigServletWebServerApplicationContext : Refreshing
org.springframework.boot.web.servlet.context.AnnotationConfigServletWebServerApplicationContext@6e5a8246:

Started SampleApplication in 2.992 seconds (JVM running for 3.658)
```

By default, INFO logging messages are shown, including some relevant startup details, such as the user that launched the application. If you need a log level other than INFO, you can set it, as described in Section 26.4, "Log Levels",

23.1 Startup Failure

If your application fails to start, registered FailureAnalyzers get a chance to provide a dedicated error message and a concrete action to fix the problem. For instance, if you start a web application on port 8080 and that port is already in use, you should see something similar to the following message:

```
*************************************

APPLICATION FAILED TO START

*****************************

Description:

Embedded servlet container failed to start. Port 8080 was already in use.

Action:

Identify and stop the process that's listening on port 8080 or configure this application to listen on another port.
```

Note

Spring Boot provides numerous FailureAnalyzer implementations, and you can add your own.

If no failure analyzers are able to handle the exception, you can still display the full conditions report to better understand what went wrong. To do

so, you need to <u>enable the debug property</u> or <u>enable DEBUG logging</u> for org.springframework.boot.autoconfigure.logging.ConditionEvaluationReportLoggingListener

For instance, if you are running your application by using java -jar, you can enable the debug property as follows:

```
$ java -jar myproject-0.0.1-SNAPSHOT.jar --debug
```

23.2 Customizing the Banner

The banner that is printed on start up can be changed by adding a banner.txt file to your classpath or by setting the spring.banner.location property to the location of such a file. If the file has an encoding other than UTF-8, you can set spring.banner.charset. In addition to a text file, you can also add a banner.gif, banner.jpg, or banner.png image file to your classpath or set the spring.banner.image.location property. Images are converted into an ASCII art representation and printed above any text banner.

Inside your banner.txt file, you can use any of the following placeholders:

Table 23.1. Banner variables

Variable	Description
\${application.version}	The version number of your application, as declared in MANIFEST.MF. For example, Implementation-Version: 1.0 is printed as 1.0.
\${application.formatted-version}	The version number of your application, as declared in MANIFEST.MF and formatted for display (surrounded with brackets and prefixed with v). For example (v1.0).
<pre>\${spring-boot.version}</pre>	The Spring Boot version that you are using. For example 2.0.0.BUILD-SNAPSHOT.
\${spring-boot.formatted-version}	The Spring Boot version that you are using, formatted for display (surrounded with brackets and prefixed with v). For example (v2.0.0.BUILD-SNAPSHOT).
<pre>\${Ansi.NAME} (or \${AnsiColor.NAME}, \${AnsiBackground.NAME}, \${AnsiStyle.NAME})</pre>	Where NAME is the name of an ANSI escape code. See AnsiPropertySource for details.
\${application.title}	The title of your application, as declared in MANIFEST.MF. For example Implementation-Title: MyApp is printed as MyApp.

Tip

The SpringApplication.setBanner(...) method can be used if you want to generate a banner programmatically. Use the org.springframework.boot.Banner interface and implement your own printBanner() method.

You can also use the spring.main.banner-mode property to determine if the banner has to be printed on System.out (console), sent to the configured logger (log), or not produced at all (off).

The printed banner is registered as a singleton bean under the following name: springBootBanner.

Note

YAML maps off to false, so be sure to add quotes if you want to disable the banner in your application, as shown in the following example:

```
spring:
main:
banner-mode: "off"
```

23.3 Customizing SpringApplication

If the SpringApplication defaults are not to your taste, you can instead create a local instance and customize it. For example, to turn off the banner, you could write:

```
public static void main(String[] args) {
   SpringApplication app = new SpringApplication(MySpringConfiguration.class);
   app.setBannerMode(Banner.Mode.OFF);
   app.run(args);
}
```

Note

The constructor arguments passed to SpringApplication are configuration sources for Spring beans. In most cases, these are references to @Configuration classes, but they could also be references to XML configuration or to packages that should be scanned.

It is also possible to configure the SpringApplication by using an application.properties file. See *Chapter 24, Externalized Configuration* for details.

For a complete list of the configuration options, see the SpringApplication_Javadoc.

23.4 Fluent Builder API

If you need to build an ApplicationContext hierarchy (multiple contexts with a parent/child relationship) or if you prefer using a "fluent" builder API, you can use the SpringApplicationBuilder.

The SpringApplicationBuilder lets you chain together multiple method calls and includes parent and child methods that let you create a hierarchy, as shown in the following example:

```
new SpringApplicationBuilder()
   .sources(Parent.class)
   .child(Application.class)
   .bannerMode(Banner.Mode.OFF)
   .run(args);
```

Note

There are some restrictions when creating an ApplicationContext hierarchy. For example, Web components **must** be contained within the child context, and the same Environment is

used for both parent and child contexts. See the SpringApplicationBuilder Javadoc for full details.

23.5 Application Events and Listeners

In addition to the usual Spring Framework events, such as ContextRefreshedEvent, a SpringApplication sends some additional application events.

Note

Some events are actually triggered before the ApplicationContext is created, so you cannot register a listener on those as a @Bean. You can register them with the SpringApplication.addListeners(...) method or the SpringApplicationBuilder.listeners(...) method.

If you want those listeners to be registered automatically, regardless of the way the application is created, you can add a META-INF/spring.factories file to your project and reference your listener(s) by using the org.springframework.context.ApplicationListener key, as shown in the following example:

org.springframework.context.ApplicationListener=com.example.project.MyListener

Application events are sent in the following order, as your application runs:

- 1. An ApplicationStartingEvent is sent at the start of a run but before any processing, except for the registration of listeners and initializers.
- 2. An ApplicationEnvironmentPreparedEvent is sent when the Environment to be used in the context is known but before the context is created.
- 3. An ApplicationPreparedEvent is sent just before the refresh is started but after bean definitions have been loaded.
- 4. An ApplicationStartedEvent is sent after the context has been refreshed but before any application and command-line runners have been called.
- 5. An ApplicationReadyEvent is sent after any application and command-line runners have been called. It indicates that the application is ready to service requests.
- 6. An ApplicationFailedEvent is sent if there is an exception on startup.

Tip

You often need not use application events, but it can be handy to know that they exist. Internally, Spring Boot uses events to handle a variety of tasks.

Application events are sent by using Spring Framework's event publishing mechanism. Part of this mechanism ensures that an event published to the listeners in a child context is also published to the listeners in any ancestor contexts. As a result of this, if your application uses a hierarchy of SpringApplication instances, a listener may receive multiple instances of the same type of application event.

To allow your listener to distinguish between an event for its context and an event for a descendant context, it should request that its application context is injected and then compare

the injected context with the context of the event. The context can be injected by implementing ApplicationContextAware or, if the listener is a bean, by using @Autowired.

23.6 Web Environment

A SpringApplication attempts to create the right type of ApplicationContext on your behalf. By default, an AnnotationConfigApplicationContext or AnnotationConfigServletWebServerApplicationContext is used, depending on whether you are developing a web application or not.

The algorithm used to determine a "web environment" is fairly simplistic (it is based on the presence of a few classes). If you need to override the default, you can use <code>setWebEnvironment(boolean webEnvironment)</code>.

It is also possible to take complete control of the ApplicationContext type that is used by calling setApplicationContextClass(...).

Tip

It is often desirable to call setWebEnvironment(false) when using SpringApplication within a JUnit test.

23.7 Accessing Application Arguments

If you need to access the application arguments that were passed to SpringApplication.run(...), you can inject a org.springframework.boot.ApplicationArguments bean. The ApplicationArguments interface provides access to both the raw String[] arguments as well as parsed option and non-option arguments, as shown in the following example:

```
import org.springframework.boot.*
import org.springframework.beans.factory.annotation.*
import org.springframework.stereotype.*

@Component
public class MyBean {

@Autowired
public MyBean(ApplicationArguments args) {
  boolean debug = args.containsOption("debug");
  List<String> files = args.getNonOptionArgs();
  // if run with "--debug logfile.txt" debug=true, files=["logfile.txt"]
}
```

Tip

Spring Boot also registers a CommandLinePropertySource with the Spring Environment. This lets you also inject single application arguments by using the @Value annotation.

23.8 Using the ApplicationRunner or CommandLineRunner

If you need to run some specific code once the SpringApplication has started, you can implement the ApplicationRunner or CommandLineRunner interfaces. Both interfaces work in the same way and offer a single run method, which is called just before SpringApplication.run(...) completes.

The CommandLineRunner interfaces provides access to application arguments as a simple string array, whereas the ApplicationRunner uses the ApplicationArguments interface discussed earlier. The following example shows a CommandLineRunner with a run method:

```
import org.springframework.boot.*
import org.springframework.stereotype.*

@Component
public class MyBean implements CommandLineRunner {

public void run(String... args) {
    // Do something...
}
```

If several CommandLineRunner or ApplicationRunner beans are defined that must be called in a specific order, you can additionally implement the org.springframework.core.Ordered interface or use the org.springframework.core.annotation.Order annotation.

23.9 Application Exit

Each SpringApplication registers a shutdown hook with the JVM to ensure that the ApplicationContext closes gracefully on exit. All the standard Spring lifecycle callbacks (such as the DisposableBean interface or the @PreDestroy annotation) can be used.

In addition, beans may implement the org.springframework.boot.ExitCodeGenerator interface if they wish to return a specific exit code when SpringApplication.exit() is called. This exit code can then be passed to System.exit() to return it as a status code, as shown in the following example:

```
@SpringBootApplication
public class ExitCodeApplication {

@Bean
public ExitCodeGenerator exitCodeGenerator() {
  return () -> 42;
}

public static void main(String[] args) {
  System.exit(SpringApplication
    .exit(SpringApplication.run(ExitCodeApplication.class, args)));
}
```

Also, the <code>ExitCodeGenerator</code> interface may be implemented by exceptions. When such an exception is encountered, Spring Boot returns the exit code provided by the implemented <code>getExitCode()</code> method.

23.10 Admin Features

enable admin-related lt is possible to features for the application by spring.application.admin.enabled property. This exposes the SpringApplicationAdminMXBean on the platform MBeanServer. You could use this feature to administer your Spring Boot application remotely. This feature could also be useful for any service wrapper implementation.

Tip

If you want to know on which HTTP port the application is running, get the property with a key of local.server.port.

Caution

Take care when enabling this feature, as the MBean exposes a method to shutdown the application.

24. Externalized Configuration

Spring Boot lets you externalize your configuration so that you can work with the same application code in different environments. You can use properties files, YAML files, environment variables, and command-line arguments to externalize configuration. Property values can be injected directly into your beans by using the @Value annotation, accessed through Spring's Environment abstraction, or be bound to structured objects through @ConfigurationProperties.

Spring Boot uses a very particular PropertySource order that is designed to allow sensible overriding of values. Properties are considered in the following order:

- 1. <u>Devtools global settings properties</u> on your home directory (~/.spring-boot-devtools.properties when devtools is active).
- 2. @TestPropertySource annotations on your tests.
- 3. @SpringBootTest#properties annotation attribute on your tests.
- 4. Command line arguments.
- 5. Properties from SPRING_APPLICATION_JSON (inline JSON embedded in an environment variable or system property).
- 6. ServletConfig init parameters.
- 7. ServletContext init parameters.
- 8. JNDI attributes from java:comp/env.
- 9. Java System properties (System.getProperties()).
- 10.OS environment variables.
- 11A RandomValuePropertySource that has properties only in random. *.
- 12<u>Profile-specific application properties</u> outside of your packaged jar (application-fprofile).properties and YAML variants).
- 13<u>Profile-specific application properties</u> packaged inside your jar (application-{profile}.properties and YAML variants).
- 14Application properties outside of your packaged jar (application.properties and YAML variants).
- 15Application properties packaged inside your jar (application.properties and YAML variants).
- 16@PropertySource annotations on your @Configuration classes.
- 17Default properties (specified by setting SpringApplication.setDefaultProperties).

To provide a concrete example, suppose you develop a @Component that uses a name property, as shown in the following example:

```
import org.springframework.stereotype.*
import org.springframework.beans.factory.annotation.*
```

```
@Component
public class MyBean {

    @Value("${name}")
    private String name;

    // ...
}
```

On your application classpath (for example, inside your jar) you can have an application.properties file that provides a sensible default property value for name. When running in a new environment, an application.properties file can be provided outside of your jar that overrides the name. For one-off testing, you can launch with a specific command line switch (for example, java -jar app.jar --name="Spring").

Tip

The SPRING_APPLICATION_JSON properties can be supplied on the command line with an environment variable. For example, you could use the following line in a UN*X shell:

```
$ SPRING_APPLICATION_JSON='{"acme":{"name":"test"}}' java -jar myapp.jar
```

In the preceding example, you end up with acme.name=test in the Spring Environment. You can also supply the JSON as spring.application.json in a System property, as shown in the following example:

```
$ java -Dspring.application.json='{"name":"test"}' -jar myapp.jar
```

You can also supply the JSON by using a command line argument, as shown in the following example:

```
$ java -jar myapp.jar --spring.application.json='{"name":"test"}'
```

You can also supply the JSON as a JNDI variable, as follows: java:comp/env/spring.application.json.

24.1 Configuring Random Values

The RandomValuePropertySource is useful for injecting random values (for example, into secrets or test cases). It can produce integers, longs, uuids, or strings, as shown in the following example:

```
my.secret=${random.value}
my.number=${random.int}
my.bignumber=${random.long}
my.uuid=${random.uuid}
my.number.less.than.ten=${random.int(10)}
my.number.in.range=${random.int[1024,65536]}
```

The random.int* syntax is OPEN value (, max) CLOSE where the OPEN, CLOSE are any character and value, max are integers. If max is provided, then value is the minimum value and max is the maximum value (exclusive).

24.2 Accessing Command Line Properties

By default, SpringApplication converts any command line option arguments (that is, arguments starting with --, such as --server.port=9000) to a property and adds them to the Spring

Environment. As mentioned previously, command line properties always take precedence over other property sources.

If you do not want command line properties to be added to the Environment, you can disable them by using SpringApplication.setAddCommandLineProperties(false).

24.3 Application Property Files

SpringApplication loads properties from application.properties files in the following locations and adds them to the Spring Environment:

- A /config subdirectory of the current directory
- 2. The current directory
- 3. A classpath /config package
- 4. The classpath root

The list is ordered by precedence (properties defined in locations higher in the list override those defined in lower locations).

Note

You can also <u>use YAML ('.yml') files</u> as an alternative to '.properties'.

If you do not like application.properties as the configuration file name, you can switch to another file name by specifying a spring.config.name environment property. You can also refer to an explicit location by using the spring.config.location environment property (which is a comma-separated list of directory locations or file paths). The following example shows how to specify a different file name:

```
$ java -jar myproject.jar --spring.config.name=myproject
```

The following example shows how to specify two locations:

```
$ java -jar myproject.jar --spring.config.location=classpath:/default.properties,classpath:/
override.properties
```

Warning

spring.config.name and spring.config.location are used very early to determine which files have to be loaded, so they must be defined as an environment property (typically an OS environment variable, a system property, or a command-line argument).

If spring.config.location contains directories (as opposed to files), they should end in / (and, at runtime, be appended with the names generated from spring.config.name before being loaded, including profile-specific file names). Files specified in spring.config.location are used as-is, with no support for profile-specific variants, and are overridden by any profile-specific properties.

Config locations are searched in reverse order. By default, the configured locations are classpath:/,classpath:/config/,file:./,file:./config/. The resulting search order is the following:

1. file: ./config/

```
2. file:./
3. classpath:/config/
4. classpath:/
```

When custom config locations are configured by using spring.config.location, they replace the default locations. For example, if spring.config.location is configured with the value classpath:/custom-config/,file:./custom-config/, the search order becomes the following:

```
    file:./custom-config/
    classpath:custom-config/
```

Alternatively, when custom config locations are configured by using <code>spring.config.additional-location</code>, they are used in addition to the default locations. Additional locations are searched before the default locations. For example, if additional locations of <code>classpath:/custom-config/,file:./custom-config/</code> are configured, the search order becomes the following:

```
    file:./custom-config/
    classpath:custom-config/
    file:./config/
    file:./
    classpath:/config/
    classpath:/
```

This search ordering lets you specify default values in one configuration file and then selectively override those values in another. You can provide default values for your application in application.properties (or whatever other basename you choose with spring.config.name) in one of the default locations. These default values can then be overridden at runtime with a different file located in one of the custom locations.

Note

If you use environment variables rather than system properties, most operating systems disallow period-separated key names, but you can use underscores instead (for example, SPRING CONFIG NAME instead of spring.config.name).

Note

If your application runs in a container, then JNDI properties (in <code>java:comp/env</code>) or servlet context initialization parameters can be used instead of, or as well as, environment variables or system properties.

24.4 Profile-specific Properties

In addition to application.properties files, profile-specific properties can also be defined by using the following naming convention: application-{profile}.properties. The Environment has

a set of default profiles (by default, [default]) that are used if no active profiles are set. In other words, if no profiles are explicitly activated, then properties from application-default.properties are loaded.

Profile-specific properties are loaded from the same locations as standard application.properties, with profile-specific files always overriding the non-specific ones, whether or not the profile-specific files are inside or outside your packaged jar.

If several profiles are specified, a last-wins strategy applies. For example, profiles specified by the spring.profiles.active property are added after those configured through the SpringApplication API and therefore take precedence.

Note

If you have specified any files in spring.config.location, profile-specific variants of those files are not considered. Use directories in spring.config.location if you want to also use profile-specific properties.

24.5 Placeholders in Properties

The values in application.properties are filtered through the existing Environment when they are used, so you can refer back to previously defined values (for example, from System properties).

```
app.name=MyApp
app.description=${app.name} is a Spring Boot application
```

Tip

You can also use this technique to create "short" variants of existing Spring Boot properties. See the <u>Section 75.4, "Use 'Short' Command Line Arguments"</u> how-to for details.

24.6 Using YAML Instead of Properties

YAML is a superset of JSON and, as such, is a convenient format for specifying hierarchical configuration data. The SpringApplication class automatically supports YAML as an alternative to properties whenever you have the <u>SnakeYAML</u> library on your classpath.

Note

If you use "Starters", SnakeYAML is automatically provided by spring-boot-starter.

Loading YAML

Spring Framework provides two convenient classes that can be used to load YAML documents. The YamlPropertiesFactoryBean loads YAML as Properties and the YamlMapFactoryBean loads YAML as a Map.

For example, consider the following YAML document:

```
environments:
    dev:
    url: http://dev.example.com
    name: Developer Setup
```

```
prod:
url: http://another.example.com
name: My Cool App
```

The preceding example would be transformed into the following properties:

```
environments.dev.url=http://dev.example.com
environments.dev.name=Developer Setup
environments.prod.url=http://another.example.com
environments.prod.name=My Cool App
```

YAML lists are represented as property keys with [index] dereferencers. For example, consider the following YAML:

```
my:
servers:
    dev.example.com
    another.example.com
```

The preceding example would be transformed into these properties:

```
my.servers[0]=dev.example.com
my.servers[1]=another.example.com
```

To bind to properties like that by using the Spring DataBinder utilities (which is what @ConfigurationProperties does), you need to have a property in the target bean of type java.util.List (or Set) and you either need to provide a setter or initialize it with a mutable value. For example, the following example binds to the properties shown previously:

```
@ConfigurationProperties(prefix="my")
public class Config {

private List<String> servers = new ArrayList<String>();

public List<String> getServers() {
   return this.servers;
  }
}
```

Note

When lists are configured in more than one place, overriding works by replacing the entire list. In the preceding example, when my.servers is defined in several places, the entire list from the PropertySource with higher precedence overrides any other configuration for that list. Both comma-separated lists and YAML lists can be used for completely overriding the contents of the list.

Exposing YAML as Properties in the Spring Environment

The YamlPropertySourceLoader class can be used to expose YAML as a PropertySource in the Spring Environment. Doing so lets you use the @Value annotation with placeholders syntax to access YAML properties.

Multi-profile YAML Documents

You can specify multiple profile-specific YAML documents in a single file by using a spring.profiles key to indicate when the document applies, as shown in the following example:

```
server:
address: 192.168.1.100
---
spring:
profiles: development
server:
address: 127.0.0.1
---
spring:
profiles: production
server:
address: 192.168.1.120
```

In the preceding example, if the development profile is active, the server.address property is 127.0.0.1. Similarly, if the production profile is active, the server.address property is 192.168.1.120. If the development and production profiles are **not** enabled, then the value for the property is 192.168.1.100.

If none are explicitly active when the application context starts, the default profiles are activated. So, in the following YAML, we set a value for <code>spring.security.user.password</code> that is available **only** in the "default" profile:

```
server:
  port: 8000
---
spring:
  profiles: default
  security:
    user:
    password: weak
```

Whereas, in the following example, the password is always set because it is not attached to any profile, and it would have to be explicitly reset in all other profiles as necessary:

```
server:
port: 8000
spring:
security:
user:
password: weak
```

Spring profiles designated by using the spring.profiles element may optionally be negated by using the ! character. If both negated and non-negated profiles are specified for a single document, at least one non-negated profile must match, and no negated profiles may match.

YAML Shortcomings

YAML files cannot be loaded by using the @PropertySource annotation. So, in the case that you need to load values that way, you need to use a properties file.

Merging YAML Lists

As <u>we showed earlier</u>, any YAML content is ultimately transformed to properties. That process may be counter-intuitive when overriding "list" properties through a profile.

For example, assume a MyPojo object with name and description attributes that are null by default. The following example exposes a list of MyPojo objects from AcmeProperties:

```
@ConfigurationProperties("acme")
public class AcmeProperties {
```

```
private final List<MyPojo> list = new ArrayList<>();

public List<MyPojo> getList() {
  return this.list;
}
```

Consider the following configuration:

```
acme:
    list:
        - name: my name
        description: my description
---
spring:
    profiles: dev
acme:
    list:
        - name: my another name
```

If the dev profile is not active, AcmeProperties.list contains one MyPojo entry, as previously defined. If the dev profile is enabled, however, the list still contains only one entry (with a name of my another name and a description of null). This configuration does not add a second MyPojo instance to the list, and it does not merge the items.

When a collection is specified in multiple profiles, the one with the highest priority (and only that one) is used. Consider the following example:

```
acme:
    list:
    - name: my name
    description: my description
    - name: another name
    description: another description
---
spring:
    profiles: dev
acme:
    list:
    - name: my another name
```

In the preceding example, if the dev profile is active, AcmeProperties.list contains one MyPojo entry (with a name of my another name and a description of null).

24.7 Type-safe Configuration Properties

Using the <code>@Value("\${property}")</code> annotation to inject configuration properties can sometimes be cumbersome, especially if you are working with multiple properties or your data is hierarchical in nature. Spring Boot provides an alternative method of working with properties that lets strongly typed beans govern and validate the configuration of your application, as shown in the following example:

```
package com.example;
import java.net.InetAddress;
import java.util.ArrayList;
import java.util.Collections;
import java.util.List;
import org.springframework.boot.context.properties.ConfigurationProperties;
@ConfigurationProperties("acme")
```

```
public class AcmeProperties {
 private boolean enabled;
 private InetAddress remoteAddress;
 private final Security security = new Security();
 public boolean isEnabled() { ... }
 public void setEnabled(boolean enabled) { ... }
 public InetAddress getRemoteAddress() { ... }
 public void setRemoteAddress(InetAddress remoteAddress) { ... }
 public Security getSecurity() { ... }
 public static class Security {
 private String username;
  private String password;
  private List<String> roles = new ArrayList<>(Collections.singleton("USER"));
 public String getUsername() { ... }
 public void setUsername(String username) { ... }
 public String getPassword() { ... }
 public void setPassword(String password) { ... }
 public List<String> getRoles() { ... }
 public void setRoles(List<String> roles) { ... }
```

The preceding POJO defines the following properties:

- acme.enabled, with a value of false by default.
- acme.remote-address, with a type that can be coerced from String.
- acme.security.username, with a nested "security" object whose name is determined by the name of the property. In particular, the return type is not used at all there and could have been SecurityProperties.
- acme.security.password.
- acme.security.roles, with a collection of String.

Note

Getters and setters are usually mandatory, since binding is through standard Java Beans property descriptors, just like in Spring MVC. A setter may be omitted in the following cases:

- Maps, as long as they are initialized, need a getter but not necessarily a setter, since they can be mutated by the binder.
- Collections and arrays can be accessed either through an index (typically with YAML) or by using a single comma-separated value (properties). In the latter case, a setter is mandatory.

We recommend to always add a setter for such types. If you initialize a collection, make sure it is not immutable (as in the preceding example).

• If nested POJO properties are initialized (like the Security field in the preceding example), a setter is not required. If you want the binder to create the instance on the fly by using its default constructor, you need a setter.

Some people use Project Lombok to add getters and setters automatically. Make sure that Lombok does not generate any particular constructor for such a type, as it is used automatically by the container to instantiate the object.

Tip

See also the differences between @Value and @ConfigurationProperties.

You also need to list the properties classes to register in the <code>@EnableConfigurationProperties</code> annotation, as shown in the following example:

```
@Configuration
@EnableConfigurationProperties(AcmeProperties.class)
public class MyConfiguration {
}
```

Note

When the <code>@ConfigurationProperties</code> bean is registered that way, the bean has a conventional name: <code><prefix>-<fqn></code>, where <code><prefix></code> is the environment key prefix specified in the <code>@ConfigurationProperties</code> annotation and <code><fqn></code> is the fully qualified name of the bean. If the annotation does not provide any prefix, only the fully qualified name of the bean is used.

The bean name in the example above is acme-com.example.AcmeProperties.

Even if the preceding configuration creates a regular bean for AcmeProperties, we recommend that @ConfigurationProperties only deal with the environment and, in particular, does not inject other beans from the context. Having said that, the @EnableConfigurationProperties annotation is also automatically applied to your project so that any existing bean annotated with @ConfigurationProperties is configured from the Environment. You could shortcut MyConfiguration by making sure AcmeProperties is already a bean, as shown in the following example:

```
@Component
@ConfigurationProperties(prefix="acme")
public class AcmeProperties {

// ... see the preceding example
}
```

This style of configuration works particularly well with the SpringApplication external YAML configuration, as shown in the following example:

```
# application.yml
acme:
  remote-address: 192.168.1.1
```

```
security:
username: admin
roles:
    USER
    ADMIN

# additional configuration as required
```

To work with @ConfigurationProperties beans, you can inject them in the same way as any other bean, as shown in the following example:

```
@Service
public class MyService {

private final AcmeProperties properties;

@Autowired
public MyService(AcmeProperties properties) {
    this.properties = properties;
}

//...

@PostConstruct
public void openConnection() {
    Server server = new Server(this.properties.getRemoteAddress());
    // ...
}
```

Tip

Using @ConfigurationProperties also lets you generate metadata files that can be used by IDEs to offer auto-completion for your own keys. See the <u>Appendix B</u>, <u>Configuration Metadata</u> appendix for details.

Third-party Configuration

As well as using <code>@ConfigurationProperties</code> to annotate a class, you can also use it on public <code>@Bean</code> methods. Doing so can be particularly useful when you want to bind properties to third-party components that are outside of your control.

To configure a bean from the Environment properties, add @ConfigurationProperties to its bean registration, as shown in the following example:

```
@ConfigurationProperties(prefix = "another")
@Bean
public AnotherComponent anotherComponent() {
    ...
}
```

Any property defined with the another prefix is mapped onto that Another Component bean in manner similar to the preceding AcmeProperties example.

Relaxed Binding

Spring Boot uses some relaxed rules for binding Environment properties to @ConfigurationProperties beans, so there does not need to be an exact match between the Environment property name and the bean property name. Common examples where this is useful

include dash-separated environment properties (for example, context-path binds to contextPath), and capitalized environment properties (for example, PORT binds to port).

For example, consider the following @ConfigurationProperties class:

```
@ConfigurationProperties(prefix="acme.my-project.person")
public class OwnerProperties {

private String firstName;

public String getFirstName() {
   return this.firstName;
 }

public void setFirstName(String firstName) {
   this.firstName = firstName;
 }
}
```

In the preceding example, the following properties names can all be used:

Table 24.1. relaxed binding

Property	Note
acme.my- project.person	Standard camel case syntaxfirstName
acme.my- project.person name	Kebab case, which is recommended for use in .properties and .yml filesfirst-
acme.my- project.person	Underscore notation, which is an alternative format for use in .properties .andstymlafiles.
ACME_MYPROJECT	២ ppeo <u>naset</u> for <u>mak</u> much is recommended when using system environment variables.

Note

The prefix value for the annotation *must* be in kebab case (lowercase and separated by -, such as acme.my-project.person).

Table 24.2. relaxed binding rules per property source

Property Source	Simple	List
Properties Files	Camel case, kebab case, or underscore notation	Standard list syntax using [] or comma-separated values
YAML Files	Camel case, kebab case, or underscore notation	Standard YAML list syntax or comma- separated values
Environment Variables	Upper case format with underscore as the delimiter should not be used within a property name	Numeric values surrounded by underscores, such as MY_ACME_1_OTHER = my.acme[1].other

Property Source	Simple	List
System properties	Camel case, kebab case, or underscore notation	Standard list syntax using [] or comma-separated values

Tip

We recommend that, when possible, properties are stored in lower-case kebab format, such as my.property-name=acme.

Properties Conversion

Spring attempts to coerce the external application properties to the right type when it binds to the @ConfigurationProperties beans. If you need custom type conversion, you can provide a ConversionService bean (with a bean named conversionService) or custom property editors (through a CustomEditorConfigurer bean) or custom Converters (with bean definitions annotated as @ConfigurationPropertiesBinding).

Note

As this bean is requested very early during the application lifecycle, make sure to limit the dependencies that your ConversionService is using. Typically, any dependency that you require may not be fully initialized at creation time. You may want to rename your custom ConversionService if it is not required for configuration keys coercion and only rely on custom converters qualified with @ConfigurationPropertiesBinding.

@ConfigurationProperties Validation

Spring Boot attempts to validate @ConfigurationProperties classes whenever they are annotated with Spring's @Validated annotation. You can use JSR-303 javax.validation constraint annotations directly on your configuration class. To do so, ensure that a compliant JSR-303 implementation is on your classpath and then add constraint annotations to your fields, as shown in the following example:

```
@ConfigurationProperties(prefix="acme")
@Validated
public class AcmeProperties {

@NotNull
private InetAddress remoteAddress;

// ... getters and setters
}
```

In order to validate the values of nested properties, you must annotate the associated field as @Valid to trigger its validation. The following example builds on the preceding AcmeProperties example:

```
@ConfigurationProperties(prefix="acme")
@Validated
public class AcmeProperties {

@NotNull
private InetAddress remoteAddress;

@Valid
```

```
private final Security security = new Security();

// ... getters and setters

public static class Security {

@NotEmpty
public String username;

// ... getters and setters
}
```

You can also add a custom Spring Validator by creating a bean definition called configurationPropertiesValidator. The @Bean method should be declared static. The configuration properties validator is created very early in the application's lifecycle, and declaring the @Bean method as static lets the bean be created without having to instantiate the @Configuration class. Doing so avoids any problems that may be caused by early instantiation. There is a property validation sample that shows how to set things up.

Tip

The spring-boot-actuator module includes an endpoint that exposes all @ConfigurationProperties beans. Point your web browser to /actuator/configprops or use the equivalent JMX endpoint. See the "Production ready features" section for details.

@ConfigurationProperties vs. @Value

The @Value annotation is a core container feature, and it does not provide the same features as type-safe configuration properties. The following table summarizes the features that are supported by @ConfigurationProperties and @Value:

Feature	@ConfigurationPrope@Walkse	
Relaxed binding	Yes	No
Meta-data support	Yes	No
SpEL evaluation	No	Yes

If you define a set of configuration keys for your own components, we recommend you group them in a POJO annotated with <code>@ConfigurationProperties</code>. You should also be aware that, since <code>@Value</code> does not support relaxed binding, it is not a good candidate if you need to provide the value by using environment variables.

Finally, while you can write a SpEL expression in @Value, such expressions are not processed from application property files.

25. Profiles

Spring Profiles provide a way to segregate parts of your application configuration and make it be available only in certain environments. Any @Component or @Configuration can be marked with @Profile to limit when it is loaded, as shown in the following example:

```
@Configuration
@Profile("production")
public class ProductionConfiguration {
    // ...
}
```

You can use a spring.profiles.active Environment property to specify which profiles are active. You can specify the property in any of the ways described earlier in this chapter. For example, you could include it in your application.properties, as shown in the following example:

```
spring.profiles.active=dev,hsqldb
```

You could also specify it on the command line by using the following switch: --spring.profiles.active=dev,hsqldb.

25.1 Adding Active Profiles

The spring.profiles.active property follows the same ordering rules as other properties: The highest PropertySource wins. This means that you can specify active profiles in application.properties and then **replace** them by using the command line switch.

Sometimes, it is useful to have profile-specific properties that **add** to the active profiles rather than replace them. The <code>spring.profiles.include</code> property can be used to unconditionally add active profiles. The <code>SpringApplication</code> entry point also has a Java API for setting additional profiles (that is, on top of those activated by the <code>spring.profiles.active</code> property). See the <code>setAdditionalProfiles()</code> method in <code>SpringApplication</code>.

For example, when an application with the following properties is run by using the switch, --spring.profiles.active=prod, the proddb and prodmq profiles are also activated:

```
my.property: fromyamlfile
---
spring.profiles: prod
spring.profiles.include:
- proddb
- prodmq
```

Note

Remember that the spring.profiles property can be defined in a YAML document to determine when this particular document is included in the configuration. See <u>Section 75.7</u>, <u>"Change Configuration Depending on the Environment"</u> for more details.

25.2 Programmatically Setting Profiles

You can programmatically set active profiles by calling SpringApplication.setAdditionalProfiles(...) before your application runs. It is also possible to activate profiles by using Spring's ConfigurableEnvironment interface.

25.3 Profile-specific Configuration Files

Profile-specific variants of both application.properties (or application.yml) and files referenced through @ConfigurationProperties are considered as files and loaded. See "Section 24.4, "Profile-specific Properties" for details.

26. Logging

Spring Boot uses <u>Commons Logging</u> for all internal logging but leaves the underlying log implementation open. Default configurations are provided for <u>Java Util Logging</u>, <u>Log4J2</u>, and <u>Logback</u>. In each case, loggers are pre-configured to use console output with optional file output also available.

By default, if you use the "Starters", Logback is used for logging. Appropriate Logback routing is also included to ensure that dependent libraries that use Java Util Logging, Commons Logging, Log4J, or SLF4J all work correctly.

Tip

There are a lot of logging frameworks available for Java. Do not worry if the above list seems confusing. Generally, you do not need to change your logging dependencies and the Spring Boot defaults work just fine.

26.1 Log Format

The default log output from Spring Boot resembles the following example:

```
2014-03-05 10:57:51.112 INFO 45469 --- [ main] org.apache.catalina.core.StandardEngine : Starting Servlet Engine: Apache Tomcat/7.0.52
2014-03-05 10:57:51.253 INFO 45469 --- [ost-startStop-1] o.a.c.c.C.[Tomcat].[localhost].[/] : Initializing Spring embedded WebApplicationContext
2014-03-05 10:57:51.253 INFO 45469 --- [ost-startStop-1] o.s.web.context.ContextLoader : Root WebApplicationContext: initialization completed in 1358 ms
2014-03-05 10:57:51.698 INFO 45469 --- [ost-startStop-1] o.s.b.c.e.ServletRegistrationBean : Mapping servlet: 'dispatcherServlet' to [/]
2014-03-05 10:57:51.702 INFO 45469 --- [ost-startStop-1] o.s.b.c.embedded.FilterRegistrationBean : Mapping filter: 'hiddenHttpMethodFilter' to: [/*]
```

The following items are output:

- Date and Time: Millisecond precision and easily sortable.
- Log Level: ERROR, WARN, INFO, DEBUG, or TRACE.
- Process ID.
- A --- separator to distinguish the start of actual log messages.
- Thread name: Enclosed in square brackets (may be truncated for console output).
- Logger name: This is usually the source class name (often abbreviated).
- The log message.

Note

Logback does not have a FATAL level. It is mapped to ERROR.

26.2 Console Output

The default log configuration echoes messages to the console as they are written. By default, ERROR-level, WARN-level, and INFO-level messages are logged. You can also enable a "debug" mode by starting your application with a --debug flag.

```
$ java -jar myapp.jar --debug
```

Note

You can also specify debug=true in your application.properties.

When the debug mode is enabled, a selection of core loggers (embedded container, Hibernate, and Spring Boot) are configured to output more information. Enabling the debug mode does *not* configure your application to log all messages with DEBUG level.

Alternatively, you can enable a "trace" mode by starting your application with a --trace flag (or trace=true in your application.properties). Doing so enables trace logging for a selection of core loggers (embedded container, Hibernate schema generation, and the whole Spring portfolio).

Color-coded Output

If your terminal supports ANSI, color output is used to aid readability. You can set spring.output.ansi.enabled to a supported value to override the auto detection.

Color coding is configured by using the %clr conversion word. In its simplest form, the converter colors the output according to the log level, as shown in the following example:

```
%clr(%5p)
```

The following table describes the mapping of log levels to colors:

Level	Color
FATAL	Red
ERROR	Red
WARN	Yellow
INFO	Green
DEBUG	Green
TRACE	Green

Alternatively, you can specify the color or style that should be used by providing it as an option to the conversion. For example, to make the text yellow, use the following setting:

```
%clr(%d{yyyy-MM-dd HH:mm:ss.SSS}){yellow}
```

The following colors and styles are supported:

- blue
- cyan
- faint
- green

- magenta
- red
- yellow

26.3 File Output

By default, Spring Boot logs only to the console and does not write log files. If you want to write log files in addition to the console output, you need to set a logging.file or logging.path property (for example, in your application.properties).

The following table shows how the logging. * properties can be used together:

Table 26.1. Logging properties

logging.fi	l b ogging.pa	t E xample	Description
(none)	(none)		Console only logging.
Specific file	(none)	my.log	Writes to the specified log file. Names can be an exact location or relative to the current directory.
(none)	Specific directory	/var/log	Writes spring.log to the specified directory. Names can be an exact location or relative to the current directory.

Log files rotate when they reach 10 MB and, as with console output, ERROR-level, WARN-level, and INFO-level messages are logged by default. Size limits can be changed using the logging.file.max-size property. Previously rotated files are archived indefinitely unless the logging.file.max-history property has been set.

Note

The logging system is initialized early in the application lifecycle. Consequently, logging properties are not found in property files loaded through @PropertySource annotations.

Tip

Logging properties are independent of the actual logging infrastructure. As a result, specific configuration keys (such as logback.configurationFile for Logback) are not managed by spring Boot.

26.4 Log Levels

All the supported logging systems can have the logger levels set in the Spring Environment (for example, in application.properties) by using logging.level.*=LEVEL where LEVEL is one of TRACE, DEBUG, INFO, WARN, ERROR, FATAL, or OFF. The root logger can be configured by using logging.level.root. The following example shows potential logging settings in application.properties:

```
logging.level.root=WARN
logging.level.org.springframework.web=DEBUG
logging.level.org.hibernate=ERROR
```

26.5 Custom Log Configuration

The various logging systems can be activated by including the appropriate libraries on the classpath and can be further customized by providing a suitable configuration file in the root of the classpath or in a location specified by the following Spring Environment property: logging.config.

You can force Spring Boot to use a particular logging system by using the org.springframework.boot.logging.LoggingSystem system property. The value should be the fully qualified class name of a LoggingSystem implementation. You can also disable Spring Boot's logging configuration entirely by using a value of none.

Note

Since logging is initialized **before** the ApplicationContext is created, it is not possible to control logging from @PropertySources in Spring @Configuration files. System properties and the conventional Spring Boot external configuration files work fine.)

Depending on your logging system, the following files are loaded:

Logging System	Customization
Logback	<pre>logback-spring.xml, logback- spring.groovy, logback.xml, or logback.groovy</pre>
Log4j2	log4j2-spring.xml or log4j2.xml
JDK (Java Util Logging)	logging.properties

Note

When possible, we recommend that you use the <code>-spring</code> variants for your logging configuration (for example, <code>logback-spring.xml</code> rather than <code>logback.xml</code>). If you use standard configuration locations, Spring cannot completely control log initialization.

Warning

There are known classloading issues with Java Util Logging that cause problems when running from an 'executable jar'. We recommend that you avoid it when running from an 'executable jar' if at all possible.

To help with the customization, some other properties are transferred from the Spring Environment to System properties, as described in the following table:

Spring Environment	System Property	Comments
logging.exception-conversion-word	LOG_EXCEPTION_CONVERSION_	_₩ħ₽₽conversion word used when logging exceptions.
logging.file	LOG_FILE	If defined, it is used in the default log configuration.

Spring Environment	System Property	Comments
logging.file.max-size	LOG_FILE_MAX_SIZE	Maximum log file size (if LOG_FILE enabled). (Only supported with the default Logback setup.)
logging.file.max-history	LOG_FILE_MAX_HISTORY	Maximum number of archive log files to keep (if LOG_FILE enabled). (Only supported with the default Logback setup.)
logging.path	LOG_PATH	If defined, it is used in the default log configuration.
logging.pattern.console	CONSOLE_LOG_PATTERN	The log pattern to use on the console (stdout). (Only supported with the default Logback setup.)
logging.pattern.dateform	aLOG_DATEFORMAT_PATTERN	Appender pattern for log date format. (Only supported with the default Logback setup.)
logging.pattern.file	FILE_LOG_PATTERN	The log pattern to use in a file (if LOG_FILE is enabled). (Only supported with the default Logback setup.)
logging.pattern.level	LOG_LEVEL_PATTERN	The format to use when rendering the log level (default %5p). (Only supported with the default Logback setup.)
PID	PID	The current process ID (discovered if possible and when not already defined as an OS environment variable).

All the supported logging systems can consult System properties when parsing their configuration files. See the default configurations in spring-boot.jar for examples:

- Logback
- Log4j 2
- Java Util logging

Tip

If you want to use a placeholder in a logging property, you should use <u>Spring Boot's syntax</u> and not the syntax of the underlying framework. Notably, if you use Logback, you should use: as the delimiter between a property name and its default value and not use: -.

Tip

You can add MDC and other ad-hoc content to log lines by overriding only the LOG_LEVEL_PATTERN (or logging.pattern.level with Logback). For example, if you use logging.pattern.level=user:%X{user} %5p, then the default log format contains an MDC entry for "user", if it exists, as shown in the following example.

```
2015-09-30 12:30:04.031 user:someone INFO 22174 --- [ nio-8080-exec-0] demo.Controller Handling authenticated request
```

26.6 Logback Extensions

Spring Boot includes a number of extensions to Logback that can help with advanced configuration. You can use these extensions in your logback-spring.xml configuration file.

Note

Because the standard logback.xml configuration file is loaded too early, you cannot use extensions in it. You need to either use logback-spring.xml or define a logging.config property.

Warning

The extensions cannot be used with Logback's <u>configuration scanning</u>. If you attempt to do so, making changes to the configuration file results in an error similar to one of the following being logged:

```
ERROR in ch.qos.logback.core.joran.spi.Interpreter@4:71 - no applicable action for [springProperty], current ElementPath is [[configuration][springProperty]]

ERROR in ch.qos.logback.core.joran.spi.Interpreter@4:71 - no applicable action for [springProfile], current ElementPath is [[configuration][springProfile]]
```

Profile-specific Configuration

The <springProfile> tag lets you optionally include or exclude sections of configuration based on the active Spring profiles. Profile sections are supported anywhere within the <configuration> element. Use the name attribute to specify which profile accepts the configuration. Multiple profiles can be specified with a comma-separated list. The following listing shows three sample profiles:

```
<springProfile name="staging">
  <!-- configuration to be enabled when the "staging" profile is active -->
  </springProfile>

<springProfile name="dev, staging">
  <!-- configuration to be enabled when the "dev" or "staging" profiles are active -->
  </springProfile>

<springProfile name="!production">
  <!-- configuration to be enabled when the "production" profile is not active -->
  </springProfile>
```

Environment Properties

The <springProperty> tag lets you expose properties from the Spring Environment for use within Logback. Doing so can be useful if you want to access values from your application.properties file in your Logback configuration. The tag works in a similar way to Logback's standard property>

tag. However, rather than specifying a direct value, you specify the source of the property (from the Environment). If you need to store the property somewhere other than in local scope, you can use the scope attribute. If you need a fallback value (in case the property is not set in the Environment), you can use the defaultValue attribute. The following example shows how to expose properties for use within Logback:

Note

The source must be specified in kebab case (such as my.property-name). However, properties can be added to the Environment by using the relaxed rules.

27. Developing Web Applications

Spring Boot is well suited for web application development. You can create a self-contained HTTP server by using embedded Tomcat, Jetty, Undertow, or Netty. Most web applications use the spring-boot-starter-web module to get up and running quickly. You can also choose to build reactive web applications by using the spring-boot-starter-webflux module.

If you have not yet developed a Spring Boot web application, you can follow the "Hello World!" example in the *Getting started* section.

27.1 The "Spring Web MVC Framework"

The <u>Spring Web MVC framework</u> (often referred to as simply "Spring MVC") is a rich "model view controller" web framework. Spring MVC lets you create special @Controller or @RestController beans to handle incoming HTTP requests. Methods in your controller are mapped to HTTP by using @RequestMapping annotations.

The following code shows a typical @RestController that serves JSON data:

```
@RestController
@RequestMapping(value="/users")
public class MyRestController {

@RequestMapping(value="/{user}", method=RequestMethod.GET)
public User getUser(@PathVariable Long user) {
    // ...
}

@RequestMapping(value="/{user}/customers", method=RequestMethod.GET)
List<Customer> getUserCustomers(@PathVariable Long user) {
    // ...
}

@RequestMapping(value="/{user}", method=RequestMethod.DELETE)
public User deleteUser(@PathVariable Long user) {
    // ...
}
```

Spring MVC is part of the core Spring Framework, and detailed information is available in the <u>reference</u> documentation. There are also several guides that cover Spring MVC available at spring.io/guides.

Spring MVC Auto-configuration

Spring Boot provides auto-configuration for Spring MVC that works well with most applications.

The auto-configuration adds the following features on top of Spring's defaults:

- Inclusion of ContentNegotiatingViewResolver and BeanNameViewResolver beans.
- Support for serving static resources, including support for WebJars (covered <u>later in this document</u>)).
- Automatic registration of Converter, GenericConverter, and Formatter beans.
- Support for HttpMessageConverters (covered later in this document).
- Automatic registration of MessageCodesResolver (covered later in this document).

- Static index.html support.
- Custom Favicon support (covered <u>later in this document</u>).
- Automatic use of a ConfigurableWebBindingInitializer bean (covered <u>later in this</u> <u>document</u>).

If you want to keep Spring Boot MVC features and you want to add additional MVC configuration (interceptors, formatters, view controllers, and other features), you can add your own @Configuration class of type WebMvcConfigurer but without @EnableWebMvc. If you wish to provide custom instances of RequestMappingHandlerMapping, RequestMappingHandlerAdapter, or ExceptionHandlerExceptionResolver, you can declare a WebMvcRegistrationsAdapter instance to provide such components.

If you want to take complete control of Spring MVC, you can add your own @Configuration annotated with @EnableWebMvc.

HttpMessageConverters

Spring MVC uses the HttpMessageConverter interface to convert HTTP requests and responses. Sensible defaults are included out of the box. For example, objects can be automatically converted to JSON (by using the Jackson library) or XML (by using the Jackson XML extension, if available, or by using JAXB if the Jackson XML extension is not available). By default, strings are encoded in UTF-8.

If you need to add or customize converters, you can use Spring Boot's HttpMessageConverters class, as shown in the following listing:

```
import org.springframework.boot.autoconfigure.web.HttpMessageConverters;
import org.springframework.context.annotation.*;
import org.springframework.http.converter.*;

@Configuration
public class MyConfiguration {

@Bean
public HttpMessageConverters customConverters() {
   HttpMessageConverter<?> additional = ...
   HttpMessageConverter<?> another = ...
   return new HttpMessageConverters(additional, another);
}
```

Any HttpMessageConverter bean that is present in the context is added to the list of converters. You can also override default converters in the same way.

Custom JSON Serializers and Deserializers

If you use Jackson to serialize and deserialize JSON data, you might want to write your own <code>JsonSerializer</code> and <code>JsonDeserializer</code> classes. Custom serializers are usually registered with <code>Jackson</code> through a module, but Spring Boot provides an alternative <code>@JsonComponent</code> annotation that makes it easier to directly register Spring Beans.

You can use the @JsonComponent annotation directly on JsonSerializer or JsonDeserializer implementations. You can also use it on classes that contain serializers/deserializers as inner classes, as shown in the following example:

```
import java.io.*;
import com.fasterxml.jackson.core.*;
import com.fasterxml.jackson.databind.*;
import org.springframework.boot.jackson.*;

@JsonComponent
public class Example {

public static class Serializer extends JsonSerializer<SomeObject> {

// ...
}

public static class Deserializer extends JsonDeserializer<SomeObject> {

// ...
}
```

All @JsonComponent beans in the ApplicationContext are automatically registered with Jackson. Because @JsonComponent is meta-annotated with @Component, the usual component-scanning rules apply.

Spring Boot also provides <u>JsonObjectSerializer</u> and <u>JsonObjectDeserializer</u> base classes that provide useful alternatives to the standard Jackson versions when serializing objects. See <u>JsonObjectSerializer</u> and <u>JsonObjectDeserializer</u> in the Javadoc for details.

MessageCodesResolver

Spring MVC has a strategy for generating error codes for rendering error messages from binding errors: MessageCodesResolver. If you set the spring.mvc.message-codes-resolver.format property PREFIX_ERROR_CODE or POSTFIX_ERROR_CODE, Spring Boot creates one for you (see the enumeration in DefaultMessageCodesResolver.Format).

Static Content

By default, Spring Boot serves static content from a directory called /static (or /public or / resources or /META-INF/resources) in the classpath or from the root of the ServletContext. It uses the ResourceHttpRequestHandler from Spring MVC so that you can modify that behavior by adding your own WebMvcConfigurer and overriding the addResourceHandlers method.

In a stand-alone web application, the default servlet from the container is also enabled and acts as a fallback, serving content from the root of the ServletContext if Spring decides not to handle it. Most of the time, this does not happen (unless you modify the default MVC configuration), because Spring can always handle requests through the DispatcherServlet.

By default, resources are mapped on /**, but you can tune that with the spring.mvc.static-path-pattern property. For instance, relocating all resources to /resources/** can be achieved as follows:

```
spring.mvc.static-path-pattern=/resources/**
```

You can also customize the static resource locations by using the spring.resources.static-locations property (replacing the default values with a list of directory locations). The root Servlet context path, "/", is automatically added as a location as well.

In addition to the "standard" static resource locations mentioned earlier, a special case is made for <u>Webjars content</u>. Any resources with a path in /webjars/** are served from jar files if they are packaged in the Webjars format.

Tip

Do not use the src/main/webapp directory if your application is packaged as a jar. Although
this directory is a common standard, it works only with war packaging, and it is silently ignored
by most build tools if you generate a jar.

Spring Boot also supports the advanced resource handling features provided by Spring MVC, allowing use cases such as cache-busting static resources or using version agnostic URLs for Webjars.

To use version agnostic URLs for Webjars, add the webjars-locator dependency. Then declare your Webjar. Using jQuery as an example, adding "/webjars/jquery/dist/jquery.min.js" results in "/webjars/jquery/x.y.z/dist/jquery.min.js". where x.y.z is the Webjar version.

Note

If you use JBoss, you need to declare the webjars-locator-jboss-vfs dependency instead of the webjars-locator. Otherwise, all Webjars resolve as a 404.

To use cache busting, the following configuration configures a cache busting solution for all static resources, effectively adding a content hash, such as href="/css/spring-2a2d595e6ed9a0b24f027f2b63b134d6.css"/>, in URLs:

```
spring.resources.chain.strategy.content.enabled=true
spring.resources.chain.strategy.content.paths=/**
```

Note

Links to resources are rewritten in templates at runtime, thanks to a ResourceUrlEncodingFilter that is auto-configured for Thymeleaf and FreeMarker. You should manually declare this filter when using JSPs. Other template engines are currently not automatically supported but can be with custom template macros/helpers and the use of the ResourceUrlProvider.

When loading resources dynamically with, for example, a JavaScript module loader, renaming files is not an option. That is why other strategies are also supported and can be combined. A "fixed" strategy adds a static version string in the URL without changing the file name, as shown in the following example:

```
spring.resources.chain.strategy.content.enabled=true
spring.resources.chain.strategy.content.paths=/**
spring.resources.chain.strategy.fixed.enabled=true
spring.resources.chain.strategy.fixed.paths=/js/lib/
spring.resources.chain.strategy.fixed.version=v12
```

With this configuration, JavaScript modules located under "/js/lib/" use a fixed versioning strategy ("/v12/js/lib/mymodule.js"), while other resources still use the content one (href="/css/spring-2a2d595e6ed9a0b24f027f2b63b134d6.css"/>).

See ResourceProperties for more supported options.

Tip

This feature has been thoroughly described in a dedicated <u>blog post</u> and in Spring Framework's <u>reference documentation</u>.

Welcome Page

Spring Boot supports both static and templated welcome pages. It first looks for an index.html file in the configured static content locations. If one is not found, it then looks for an index template. If either is found, it is automatically used as the welcome page of the application.

Custom Favicon

Spring Boot looks for a favicon.ico in the configured static content locations and the root of the classpath (in that order). If such a file is present, it is automatically used as the favicon of the application.

Path Patching and Content Negotiation

Spring MVC can map incoming HTTP requests to handlers by looking at the request path and matching it to the mappings defined in your application (for example, @GetMapping annotations on Controller methods).

Spring Boot chooses to disable suffix pattern matching by default, which means that requests like "GET /projects/spring-boot.json" won't be matched to @GetMapping("/project/spring-boot") mappings. This is considered as a best practice for Spring MVC applications. This feature was mainly useful in the past for HTTP clients which did not send proper "Accept" request headers; we needed to make sure to send the correct Content Type to the client. Nowadays, Content Negotiation is much more reliable.

There are other ways to deal with HTTP clients that don't consistently send proper "Accept" request headers. Instead of using suffix matching, we can use a query parameter to ensure that requests like "GET /projects/spring-boot?format=json" will be mapped to @GetMapping("/project/spring-boot"):

```
# We can change the parameter name, which is "format" by default:
# spring.mvc.content-negotiation.parameter-name=myparam

# We can also register additional file extensions/media types with:
spring.mvc.content-negotiation.media-types.markdown
```

If you understand the caveats and would still like your application to use suffix pattern matching, the following configuration is required:

```
# You can also restrict that feature to known extensions only
# spring.mvc.path-match.use-registered-suffix-pattern=true

# We can also register additional file extensions/media types with:
# spring.mvc.content-negotiation.media-types.adoc=text/asciidoc
```

ConfigurableWebBindingInitializer

Spring MVC uses a WebBindingInitializer to initialize a WebDataBinder for a particular request. If you create your own ConfigurableWebBindingInitializer @Bean, Spring Boot automatically configures Spring MVC to use it.

Template Engines

As well as REST web services, you can also use Spring MVC to serve dynamic HTML content. Spring MVC supports a variety of templating technologies, including Thymeleaf, FreeMarker, and JSPs. Also, many other templating engines include their own Spring MVC integrations.

Spring Boot includes auto-configuration support for the following templating engines:

- FreeMarker
- Groovy
- Thymeleaf
- Mustache

Tip

If possible, JSPs should be avoided. There are several <u>known limitations</u> when using them with embedded servlet containers.

When you use one of these templating engines with the default configuration, your templates are picked up automatically from src/main/resources/templates.

Tip

Depending on how you run your application, IntelliJ IDEA orders the classpath differently. Running your application in the IDE from its main method results in a different ordering than when you run your application by using Maven or Gradle or from its packaged jar. This can cause Spring Boot to fail to find the templates on the classpath. If you have this problem, you can reorder the classpath in the IDE to place the module's classes and resources first. Alternatively, you can configure the template prefix to search every templates directory on the classpath, as follows: classpath*:/templates/.

Error Handling

By default, Spring Boot provides an /error mapping that handles all errors in a sensible way, and it is registered as a "global" error page in the servlet container. For machine clients, it produces a JSON response with details of the error, the HTTP status, and the exception message. For browser clients, there is a "whitelabel" error view that renders the same data in HTML format (to customize it, add a View that resolves to error). To replace the default behavior completely, you can implement ErrorController and register a bean definition of that type or add a bean of type ErrorAttributes to use the existing mechanism but replace the contents.

Tip

The BasicErrorController can be used as a base class for a custom ErrorController. This is particularly useful if you want to add a handler for a new content type (the default is to handle text/html specifically and provide a fallback for everything else). To do so, extend BasicErrorController, add a public method with a @RequestMapping that has a produces attribute, and create a bean of your new type.

You can also define a class annotated with <code>@ControllerAdvice</code> to customize the JSON document to return for a particular controller and/or exception type, as shown in the following example:

```
@ControllerAdvice(basePackageClasses = AcmeController.class)
public class AcmeControllerAdvice extends ResponseEntityExceptionHandler {

@ExceptionHandler(YourException.class)
@ResponseBody
ResponseEntity<?> handleControllerException(HttpServletRequest request, Throwable ex) {
   HttpStatus status = getStatus(request);
   return new ResponseEntity<>(new CustomErrorType(status.value(), ex.getMessage()), status);
}

private HttpStatus getStatus(HttpServletRequest request) {
   Integer statusCode = (Integer) request.getAttribute("javax.servlet.error.status_code");
   if (statusCode == null) {
      return HttpStatus.INTERNAL_SERVER_ERROR;
   }
   return HttpStatus.valueOf(statusCode);
}
```

In the preceding example, if YourException is thrown by a controller defined in the same package as AcmeController, a JSON representation of the CustomErrorType POJO is used instead of the ErrorAttributes representation.

Custom Error Pages

If you want to display a custom HTML error page for a given status code, you can add a file to an /error folder. Error pages can either be static HTML (that is, added under any of the static resource folders) or be built by using templates. The name of the file should be the exact status code or a series mask.

For example, to map 404 to a static HTML file, your folder structure would be as follows:

```
src/
+- main/
+- java/
| + <source code>
+- resources/
+- public/
+- error/
| +- 404.html
+- <other public assets>
```

To map all 5xx errors by using a FreeMarker template, your folder structure would be as follows:

For more complex mappings, you can also add beans that implement the ErrorViewResolver interface, as shown in the following example:

```
public class MyErrorViewResolver implements ErrorViewResolver {
    @Override
    public ModelAndView resolveErrorView(HttpServletRequest request,
        HttpStatus status, Map<String, Object> model) {
```

```
// Use the request or status to optionally return a ModelAndView
return ...
}
```

You can also use regular Spring MVC features such as <u>@ExceptionHandler methods</u> and <u>@ControllerAdvice</u>. The ErrorController then picks up any unhandled exceptions.

Mapping Error Pages outside of Spring MVC

For applications that do not use Spring MVC, you can use the ErrorPageRegistrar interface to directly register ErrorPages. This abstraction works directly with the underlying embedded servlet container and works even if you do not have a Spring MVC DispatcherServlet.

```
@Bean
public ErrorPageRegistrar errorPageRegistrar(){
   return new MyErrorPageRegistrar();
}

// ...
private static class MyErrorPageRegistrar implements ErrorPageRegistrar {
   @Override
   public void registerErrorPages(ErrorPageRegistry registry) {
      registry.addErrorPages(new ErrorPage(HttpStatus.BAD_REQUEST, "/400"));
   }
}
```

Note

If you register an ErrorPage with a path that ends up being handled by a Filter (as is common with some non-Spring web frameworks, like Jersey and Wicket), then the Filter has to be explicitly registered as an ERROR dispatcher, as shown in the following example:

```
@Bean
public FilterRegistrationBean myFilter() {
  FilterRegistrationBean registration = new FilterRegistrationBean();
  registration.setFilter(new MyFilter());
  ...
  registration.setDispatcherTypes(EnumSet.allOf(DispatcherType.class));
  return registration;
}
```

Note that the default FilterRegistrationBean does not include the ERROR dispatcher type.

CAUTION:When deployed to a servlet container, Spring Boot uses its error page filter to forward a request with an error status to the appropriate error page. The request can only be forwarded to the correct error page if the response has not already been committed. By default, WebSphere Application Server 8.0 and later commits the response upon successful completion of a servlet's service method. You should disable this behavior by setting com.ibm.ws.webcontainer.invokeFlushAfterService to false.

Spring HATEOAS

If you develop a RESTful API that makes use of hypermedia, Spring Boot provides auto-configuration for Spring HATEOAS that works well with most applications. The auto-configuration replaces the need to use <code>@EnableHypermediaSupport</code> and registers a number of beans to ease building

hypermedia-based applications, including a LinkDiscoverers (for client side support) and an ObjectMapper configured to correctly marshal responses into the desired representation. The ObjectMapper is customized by setting the various spring.jackson.* properties or, if one exists, by a Jackson2ObjectMapperBuilder bean.

You can take control of Spring HATEOAS's configuration by using @EnableHypermediaSupport. Note that doing so disables the ObjectMapper customization described earlier.

CORS Support

<u>Cross-origin resource sharing</u> (CORS) is a <u>W3C specification</u> implemented by <u>most browsers</u> that lets you specify in a flexible way what kind of cross-domain requests are authorized, instead of using some less secure and less powerful approaches such as IFRAME or JSONP.

As of version 4.2, Spring MVC <u>supports CORS</u>. Using <u>controller method CORS configuration</u> with <u>@CrossOrigin</u> annotations in your Spring Boot application does not require any specific configuration. <u>Global CORS configuration</u> can be defined by registering a WebMvcConfigurer bean with a customized addCorsMappings(CorsRegistry) method, as shown in the following example:

```
@Configuration
public class MyConfiguration {

@Bean
public WebMvcConfigurer corsConfigurer() {
   return new WebMvcConfigurer() {
    @Override
   public void addCorsMappings(CorsRegistry registry) {
     registry.addMapping("/api/**");
   }
  };
};
```

27.2 The "Spring WebFlux Framework"

Spring WebFlux is the new reactive web framework introduced in Spring Framework 5.0. Unlike Spring MVC, it does not require the Servlet API, is fully asynchronous and non-blocking, and implements the Reactive Streams specification through the Reactor project.

Spring WebFlux comes in two flavors: functional and annotation-based. The annotation-based one is quite close to the Spring MVC model, as shown in the following example:

```
@RestController
@RequestMapping("/users")
public class MyRestController {

@GetMapping("/{user}")
public Mono<User> getUser(@PathVariable Long user) {
    // ...
}

@GetMapping("/{user}/customers")
Flux<Customer> getUserCustomers(@PathVariable Long user) {
    // ...
}

@DeleteMapping("/{user}")
public Mono<User> deleteUser(@PathVariable Long user) {
    // ...
}
```

"WebFlux.fn", the functional variant, separates the routing configuration from the actual handling of the requests, as shown in the following example:

```
@Configuration
public class RoutingConfiguration {

@Bean
public RouterFunction<ServerResponse> monoRouterFunction(UserHandler userHandler) {
    return route(GET("/{user}").and(accept(APPLICATION_JSON)), userHandler::getUser)
    .andRoute(GET("/{user}/customers").and(accept(APPLICATION_JSON)), userHandler::getUserCustomers)
    .andRoute(DELETE("/{user}").and(accept(APPLICATION_JSON)), userHandler::deleteUser);
}

@Component
public class UserHandler {

public Mono<ServerResponse> getUser(ServerRequest request) {
    // ...
}

public Mono<ServerResponse> getUserCustomers(ServerRequest request) {
    // ...
}

public Mono<ServerResponse> deleteUser(ServerRequest request) {
    // ...
}
```

WebFlux is part of the Spring Framework. and detailed information is available in its <u>reference</u> documentation.

Tip

You can define as many RouterFunction beans as you like to modularize the definition of the router. Beans can be ordered if you need to apply a precedence.

To get started, add the spring-boot-starter-webflux module to your application.

Note

Adding both spring-boot-starter-web and spring-boot-starter-webflux modules in your application results in Spring Boot auto-configuring Spring MVC, not WebFlux. This behavior has been chosen because many Spring developers add spring-boot-starter-webflux to their Spring MVC application to use the reactive WebClient. You can still enforce your choice by setting the chosen application type to SpringApplication.setWebApplicationType(WebApplicationType.REACTIVE).

Spring WebFlux Auto-configuration

Spring Boot provides auto-configuration for Spring WebFlux that works well with most applications.

The auto-configuration adds the following features on top of Spring's defaults:

- Configuring codecs for HttpMessageReader and HttpMessageWriter instances (described <u>later</u> in this document).
- Support for serving static resources, including support for WebJars (described <u>later in this document</u>).

If you want to keep Spring Boot WebFlux features and you want to add additional <u>WebFlux</u> configuration, you can add your own @Configuration class of type WebFluxConfigurer but **without** @EnableWebFlux.

If you want to take complete control of Spring WebFlux, you can add your own @Configuration annotated with @EnableWebFlux.

HTTP Codecs with HttpMessageReaders and HttpMessageWriters

Spring WebFlux uses the HttpMessageReader and HttpMessageWriter interfaces to convert HTTP requests and responses. They are configured with CodecConfigurer to have sensible defaults by looking at the libraries available in your classpath.

Spring Boot applies further customization by using CodecCustomizer instances. For example, spring.jackson.* configuration keys are applied to the Jackson codec.

If you need to add or customize codecs, you can create a custom CodecCustomizer component, as shown in the following example:

You can also leverage **Boot's custom JSON serializers and deserializers**.

Static Content

By default, Spring Boot serves static content from a directory called /static (or /public or / resources or /META-INF/resources) in the classpath. It uses the ResourceWebHandler from Spring WebFlux so that you can modify that behavior by adding your own WebFluxConfigurer and overriding the addResourceHandlers method.

By default, resources are mapped on /**, but you can tune that by setting the spring.webflux.static-path-pattern property. For instance, relocating all resources to / resources/** can be achieved as follows:

```
spring.webflux.static-path-pattern=/resources/**
```

You can also customize the static resource locations by using spring.resources.static-locations. Doing so replaces the default values with a list of directory locations. If you do so, the default welcome page detection switches to your custom locations. So, if there is an index.html in any of your locations on startup, it is the home page of the application.

In addition to the "standard" static resource locations listed earlier, a special case is made for <u>Webjars</u> <u>content</u>. Any resources with a path in /webjars/** are served from jar files if they are packaged in the Webjars format.

Tip

Spring WebFlux applications do not strictly depend on the Servlet API, so they cannot be deployed as war files and do not use the src/main/webapp directory.

Template Engines

As well as REST web services, you can also use Spring WebFlux to serve dynamic HTML content. Spring WebFlux supports a variety of templating technologies, including Thymeleaf, FreeMarker, and Mustache.

Spring Boot includes auto-configuration support for the following templating engines:

- FreeMarker
- Thymeleaf
- Mustache

When you use one of these templating engines with the default configuration, your templates are picked up automatically from src/main/resources/templates.

Error Handling

Spring Boot provides a WebExceptionHandler that handles all errors in a sensible way. Its position in the processing order is immediately before the handlers provided by WebFlux, which are considered last. For machine clients, it produces a JSON response with details of the error, the HTTP status, and the exception message. For browser clients, there is a "whitelabel" error handler that renders the same data in HTML format. You can also provide your own HTML templates to display errors (see the next section).

The first step to customizing this feature often involves using the existing mechanism but replacing or augmenting the error contents. For that, you can add a bean of type ErrorAttributes.

To change the error handling behavior, you can implement ErrorWebExceptionHandler and register a bean definition of that type. Because a WebExceptionHandler is quite low-level, Spring Boot also provides a convenient AbstractErrorWebExceptionHandler to let you handle errors in a WebFlux functional way, as shown in the following example:

```
public class CustomErrorWebExceptionHandler extends AbstractErrorWebExceptionHandler {

// Define constructor here

@Override
protected RouterFunction<ServerResponse> getRoutingFunction(ErrorAttributes errorAttributes) {

return RouterFunctions
   .route(aPredicate, aHandler)
   .andRoute(anotherPredicate, anotherHandler);
}
```

For a more complete picture, you can also subclass <code>DefaultErrorWebExceptionHandler</code> directly and override specific methods.

Custom Error Pages

If you want to display a custom HTML error page for a given status code, you can add a file to an / error folder. Error pages can either be static HTML (that is, added under any of the static resource folders) or built with templates. The name of the file should be the exact status code or a series mask.

For example, to map 404 to a static HTML file, your folder structure would be as follows:

To map all 5xx errors by using a Mustache template, your folder structure would be as follows:

27.3 JAX-RS and Jersey

If you prefer the JAX-RS programming model for REST endpoints, you can use one of the available implementations instead of Spring MVC. <u>Jersey</u> 1.x and <u>Apache CXF</u> work quite well out of the box if you register their <u>Servlet</u> or <u>Filter</u> as a @Bean in your application context. Jersey 2.x has some native Spring support, so we also provide auto-configuration support for it in Spring Boot, together with a starter.

To get started with Jersey 2.x, include the spring-boot-starter-jersey as a dependency and then you need one @Bean of type ResourceConfig in which you register all the endpoints, as shown in the following example:

```
@Component
public class JerseyConfig extends ResourceConfig {

public JerseyConfig() {
  register(Endpoint.class);
  }
}
```

Warning

Jersey's support for scanning executable archives is rather limited. For example, it cannot scan for endpoints in a package found in WEB-INF/classes when running an executable war file. To avoid this limitation, the packages method should not be used, and endpoints should be registered individually by using the register method, as shown in the preceding example.

For more advanced customizations, you can also register an arbitrary number of beans that implement ResourceConfigCustomizer.

All the registered endpoints should be @Components with HTTP resource annotations (@GET and others), as shown in the following example:

```
@Component
@Path("/hello")
public class Endpoint {

@GET
public String message() {
  return "Hello";
}
```

Since the Endpoint is a Spring @Component, its lifecycle is managed by Spring and you can use the @Autowired annotation to inject dependencies and use the @Value annotation to inject external configuration. By default, the Jersey servlet is registered and mapped to /*. You can change the mapping by adding @ApplicationPath to your ResourceConfig.

By default, Jersey is set up as a Servlet in a <code>@Bean</code> of type <code>ServletRegistrationBean</code> named <code>jerseyServletRegistration</code>. By default, the servlet is initialized lazily, but you can customize that behavior by setting <code>spring.jersey.servlet.load-on-startup</code>. You can disable or override that bean by creating one of your own with the same name. You can also use a filter instead of a servlet by setting <code>spring.jersey.type=filter</code> (in which case, the <code>@Bean</code> to replace or override is <code>jerseyFilterRegistration</code>). The filter has an <code>@Order</code>, which you can set with <code>spring.jersey.filter.order</code>. Both the servlet and the filter registrations can be given init parameters by using <code>spring.jersey.init.*</code> to <code>specify</code> a map of properties.

There is a <u>Jersey sample</u> so that you can see how to set things up. There is also a <u>Jersey 1.x sample</u>. Note that, in the Jersey 1.x sample, the spring-boot maven plugin has been configured to unpack some Jersey jars so that they can be scanned by the JAX-RS implementation (because the sample asks for them to be scanned in its Filter registration). If any of your JAX-RS resources are packaged as nested jars, you may need to do the same.

27.4 Embedded Servlet Container Support

Spring Boot includes support for embedded <u>Tomcat</u>, <u>Jetty</u>, and <u>Undertow</u> servers. Most developers use the appropriate "Starter" to obtain a fully configured instance. By default, the embedded server listens for HTTP requests on port 8080.

Warning

If you choose to use Tomcat on <u>CentOS</u>, be aware that, by default, a temporary directory is used to store compiled JSPs, file uploads, and so on. This directory may be deleted by tmpwatch while your application is running, leading to failures. To avoid this behavior, you may want to customize your tmpwatch configuration such that tomcat.* directories are not deleted or configure server.tomcat.basedir such that embedded Tomcat uses a different location.

Servlets, Filters, and listeners

When using an embedded servlet container, you can register servlets, filters, and all the listeners (such as HttpSessionListener) from the Servlet spec, either by using Spring beans or by scanning for Servlet components.

Registering Servlets, Filters, and Listeners as Spring Beans

Any Servlet, Filter, or servlet *Listener instance that is a Spring bean is registered with the embedded container. This can be particularly convenient if you want to refer to a value from your application.properties during configuration.

By default, if the context contains only a single Servlet, it is mapped to /. In the case of multiple servlet beans, the bean name is used as a path prefix. Filters map to /*.

If convention-based mapping is not flexible enough, you can use the <code>ServletRegistrationBean</code>, <code>FilterRegistrationBean</code>, and <code>ServletListenerRegistrationBean</code> classes for complete control.

Servlet Context Initialization

Embedded Servlet servlet containers directly execute the do not 3.0+ javax.servlet.ServletContainerInitializer interface or Spring's org.springframework.web.WebApplicationInitializer interface. This is an intentional design decision intended to reduce the risk that third party libraries designed to run inside a war may break Spring Boot applications.

lf need perform servlet context initialization Spring you in Boot application, you should register bean that implements the а org.springframework.boot.web.servlet.ServletContextInitializer The single on Startup method provides access to the ServletContext and, if necessary, can easily be used as an adapter to an existing WebApplicationInitializer.

Scanning for Servlets, Filters, and listeners

When using an embedded container, automatic registration of classes annotated with @WebServlet, @WebFilter, and @WebListener can be enabled by using @ServletComponentScan.

Tip

@ServletComponentScan has no effect in a standalone container, where the container's built-in discovery mechanisms are used instead.

The ServletWebServerApplicationContext

Under the hood, Spring Boot uses a different type of ApplicationContext for embedded servlet container support. The ServletWebServerApplicationContext is a special type of WebApplicationContext that bootstraps itself by searching for a single ServletWebServerFactory bean. Usually a TomcatServletWebServerFactory, JettyServletWebServerFactory, or UndertowServletWebServerFactory has been autoconfigured.

Note

You usually do not need to be aware of these implementation classes. Most applications are autoconfigured, and the appropriate ApplicationContext and ServletWebServerFactory are created on your behalf.

Customizing Embedded Servlet Containers

Common servlet container settings can be configured by using Spring Environment properties. Usually, you would define the properties in your application.properties file.

Common server settings include:

- Network settings: Listen port for incoming HTTP requests (server.port), interface address to bind to server.address, and so on.
- Session settings: Whether the session is persistent (server.servlet.session.persistence), session timeout (server.servlet.session.timeout), location of session data (server.servlet.session.store-dir), and session-cookie configuration (server.servlet.session.cookie.*).
- Error management: Location of the error page (server.error.path) and so on.
- SSL
- HTTP compression

Spring Boot tries as much as possible to expose common settings, but this is not always possible. For those cases, dedicated namespaces offer server-specific customizations (see server.tomcat and server.undertow). For instance, access logs can be configured with specific features of the embedded servlet container.

Tip

See the <u>ServerProperties</u> class for a complete list.

Programmatic Customization

you need programmatically configure your embedded servlet to container, register Spring bean that implements the you can WebServerFactoryCustomizer interface. WebServerFactoryCustomizer provides access to the ConfigurableServletWebServerFactory, which includes numerous customization setter methods. Dedicated variants exist for Tomcat, Jetty, and Undertow. The following example shows programmatically setting the port:

```
import org.springframework.boot.web.server.WebServerFactoryCustomizer;
import org.springframework.boot.web.servlet.server.ConfigurableServletWebServerFactory;
import org.springframework.stereotype.Component;

@Component
public class CustomizationBean implements
WebServerFactoryCustomizer<ConfigurableServletWebServerFactory> {

@Override
public void customize(ConfigurableServletWebServerFactory server) {
    server.setPort(9000);
}
```

Customizing ConfigurableServletWebServerFactory Directly

If the preceding customization techniques are too limited, you can register the TomcatServletWebServerFactory, JettyServletWebServerFactory, or UndertowServletWebServerFactory bean yourself.

```
@Bean
public ConfigurableServletWebServerFactory webServerFactory() {
   TomcatServletWebServerFactory factory = new TomcatServletWebServerFactory();
   factory.setPort(9000);
   factory.setSessionTimeout(10, TimeUnit.MINUTES);
   factory.addErrorPages(new ErrorPage(HttpStatus.NOT_FOUND, "/notfound.html"));
   return factory;
}
```

Setters are provided for many configuration options. Several protected method "hooks" are also provided should you need to do something more exotic. See the <u>source code documentation</u> for details.

JSP Limitations

When running a Spring Boot application that uses an embedded servlet container (and is packaged as an executable archive), there are some limitations in the JSP support.

- With Tomcat, it should work if you use war packaging. That is, an executable war works and is also
 deployable to a standard container (not limited to, but including Tomcat). An executable jar does not
 work because of a hard-coded file pattern in Tomcat.
- With Jetty, it should work if you use war packaging. That is, an executable war works, and is also deployable to any standard container.
- Undertow does not support JSPs.
- Creating a custom error.jsp page does not override the default view for error handling. Custom error pages should be used instead.

There is a <u>JSP sample</u> so that you can see how to set things up.

28. Security

If <u>Spring Security</u> is on the classpath, then web applications are secure by default. Spring Boot relies on Spring Security's content-negotiation strategy to determine whether to use httpBasic or formLogin. To add method-level security to a web application, you can also add @EnableGlobalMethodSecurity with your desired settings. Additional information can be found in the <u>Spring Security Reference Guide</u>.

The default AuthenticationManager has a single user. The user name is user, and the password is random and is printed at INFO level when the application starts, as shown in the following example:

Using generated security password: 78fa095d-3f4c-48b1-ad50-e24c31d5cf35

Note

If you fine-tune your logging configuration, ensure that the org.springframework.boot.autoconfigure.security category is set to log INFO-level messages. Otherwise, the default password is not printed.

You can change the username and password by providing a spring.security.user.name and spring.security.user.password.

The basic features you get by default in a web application are:

- A UserDetailsService (or ReactiveUserDetailsService in case of a WebFlux application) bean with in-memory store and a single user with a generated password (see SecurityProperties.User for the properties of the user).
- Form-based login or HTTP Basic security (depending on Content-Type) for the entire application (including actuator endpoints if actuator is on the classpath).

29. MVC Security

The default security configuration is implemented in SecurityAutoConfiguration and in the classes imported from there (SpringBootWebSecurityConfiguration for web security and AuthenticationManagerConfiguration for authentication configuration, which is also relevant in non-web applications). To switch off the default web application security configuration completely, you can add a bean of type WebSecurityConfigurerAdapter (doing so does not disable the authentication manager configuration or Actuator's security).

To also switch off the authentication manager configuration, you can add a bean of type UserDetailsService, AuthenticationProvider, or AuthenticationManager. There are several secure applications in the <u>Spring Boot samples</u> to get you started with common use cases.

Access rules can be overridden by adding a custom <code>WebSecurityConfigurerAdapter</code>. Spring Boot provides convenience methods that can be used to override access rules for actuator endpoints and static resources. <code>EndpointRequest</code> can be used to create a <code>RequestMatcher</code> that is based on the <code>management.endpoints.web.base-path</code> property. <code>StaticResourceRequest</code> can be used to create a <code>RequestMatcher</code> for static resources in commonly used locations.

30. WebFlux Security

The default security configuration is implemented in ReactiveSecurityAutoConfiguration and in the classes imported from there (WebFluxSecurityConfiguration for web security and ReactiveAuthenticationManagerConfiguration for authentication configuration, which is also relevant in non-web applications). To switch off the default web application security configuration completely, you can add a bean of type WebFilterChainProxy (doing so does not disable the authentication manager configuration or Actuator's security).

To also switch off the authentication manager configuration, you can add a bean of type ReactiveUserDetailsService Of ReactiveAuthenticationManager.

Access rules can be configured by adding a custom SecurityWebFilterChain. Spring Boot provides convenience methods that can be used to override access rules for actuator endpoints and static resources. EndpointRequest can be used to create a ServerWebExchangeMatcher that is based on the management.endpoints.web.base-path property.

30.1 OAuth2

OAuth2 is a widely used authorization framework that is supported by Spring.

Client

If you have spring-security-oauth2-client on your classpath, you can take advantage of some auto-configuration to make it easy to set up an OAuth2 Client. This configuration makes use of the properties under OAuth2ClientProperties.

You can register multiple OAuth2 clients and providers under the spring.security.oauth2.client prefix, as shown in the following example:

```
spring.security.oauth2.client.registration.my-client-1.client-id=abcd
spring.security.oauth2.client.registration.my-client-1.client-secret=password
spring.security.oauth2.client.registration.my-client-1.client-name=Client for user scope
spring.security.oauth2.client.registration.my-client-1.provider=my-oauth-provider
spring.security.oauth2.client.registration.my-client-1.scope=user
spring.security.oauth2.client.registration.my-client-1.redirect-uri-template=http://my-redirect-uri.com
spring.security.oauth2.client.registration.my-client-1.client-authentication-method=basic
spring.security.oauth2.client.registration.my-client-1.authorization-grant-type=authorization_code
spring.security.oauth2.client.registration.my-client-2.client-id=abcd
spring.security.oauth2.client.registration.my-client-2.client-secret=password
spring.security.oauth2.client.registration.my-client-2.client-name=Client for email scope
spring.security.oauth2.client.registration.my-client-2.provider=my-oauth-provider
spring.security.oauth2.client.registration.my-client-2.scope=email
spring.security.oauth2.client.registration.my-client-2.redirect-uri-template=http://my-redirect-uri.com
spring.security.oauth2.client.registration.my-client-2.client-authentication-method=basic
spring.security.oauth2.client.registration.my-client-2.authorization-grant-type=authorization_code
spring.security.oauth2.client.provider.my-oauth-provider.authorization-uri=http://my-auth-server/oauth/
authorize
spring.security.oauth2.client.provider.my-oauth-provider.token-uri=http://my-auth-server/oauth/token
spring.security.oauth2.client.provider.my-oauth-provider.user-info-uri=http://my-auth-server/userinfo
spring.security.oauth2.client.provider.my-oauth-provider.jwk-set-uri=http://my-auth-server/token_keys
{\tt spring.security.oauth2.client.provider.my-oauth-provider.user-name-attribute=name}
```

By default, Spring Security's <code>OAuth2LoginAuthenticationFilter</code> only processes URLs matching <code>/login/oauth2/code/*</code>. If you want to customize the <code>redirect-uri-template</code> to use a different pattern, you need to provide configuration to process that custom pattern. For example, you can add your own <code>WebSecurityConfigurerAdapter</code> that resembles the following:

```
public class OAuth2LoginSecurityConfig extends WebSecurityConfigurerAdapter {

@Override
protected void configure(HttpSecurity http) throws Exception {
  http
    .authorizeRequests()
    .anyRequest().authenticated()
    .and()
    .oauth2Login()
    .redirectionEndpoint()
    .baseUri("/custom-callback");
  }
}
```

For common OAuth2 and OpenID providers, including Google, Github, Facebook, and Okta, we provide a set of provider defaults (google, github, facebook, and okta, respectively).

If you do not need to customize these providers, you can set the provider attribute to the one for which you need to infer defaults. Also, if the ID of your client matches the default supported provider, Spring Boot infers that as well.

In other words, the two configurations in the following example use the Google provider:

```
spring.security.oauth2.client.registration.my-client.client-id=abcd
spring.security.oauth2.client.registration.my-client.client-secret=password
spring.security.oauth2.client.registration.my-client.provider=google
spring.security.oauth2.client.registration.google.client-id=abcd
spring.security.oauth2.client.registration.google.client-secret=password
```

30.2 Actuator Security

For security purposes, all actuators other than <code>/health</code> and <code>/info</code> are disabled by default. The <code>management.endpoints.web.expose</code> flag can be used to enable the actuators. If Spring Security is on the classpath and no other WebSecurityConfigurerAdapter is present, the actuators are secured by Spring Boot auto-config. If you define a custom <code>WebSecurityConfigurerAdapter</code>, Spring Boot auto-config will back off and you will be in full control of actuator access rules.

Note

Before setting the management.endpoints.web.expose, ensure that the exposed actuators do not contain sensitive information and/or are secured by placing them behind a firewall or by something like Spring Security.

31. Working with SQL Databases

The <u>Spring Framework</u> provides extensive support for working with SQL databases, from direct JDBC access using <code>JdbcTemplate</code> to complete "object relational mapping" technologies such as Hibernate. <u>Spring Data</u> provides an additional level of functionality: creating <code>Repository</code> implementations directly from interfaces and using conventions to generate queries from your method names.

31.1 Configure a DataSource

Java's <code>javax.sql.DataSource</code> interface provides a standard method of working with database connections. Traditionally, a 'DataSource' uses a <code>URL</code> along with some credentials to establish a database connection.

Tip

See the "How-to" section for more advanced examples, typically to take full control over the configuration of the DataSource.

Embedded Database Support

It is often convenient to develop applications by using an in-memory embedded database. Obviously, in-memory databases do not provide persistent storage. You need to populate your database when your application starts and be prepared to throw away data when your application ends.

Tip

The "How-to" section includes a section on how to initialize a database.

Spring Boot can auto-configure embedded <u>H2</u>, <u>HSQL</u>, and <u>Derby</u> databases. You need not provide any connection URLs. You need only include a build dependency to the embedded database that you want to use.

Note

If you are using this feature in your tests, you may notice that the same database is reused by your whole test suite regardless of the number of application contexts that you use. If you want to make sure that each context has a separate embedded database, you should set spring.datasource.generate-unique-name to true.

For example, the typical POM dependencies would be as follows:

```
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-data-jpa</artifactId>
  </dependency>
  <dependency>
  <groupId>org.hsqldb</groupId>
  <artifactId>hsqldb</artifactId>
  <scope>runtime</scope>
  </dependency>
</dependency></dependency></dependency></dependency>
```

Note

You need a dependency on spring-jdbc for an embedded database to be auto-configured. In this example, it is pulled in transitively through spring-boot-starter-data-jpa.

Tip

If, for whatever reason, you do configure the connection URL for an embedded database, take care to ensure that the database's automatic shutdown is disabled. If you use H2, you should use DB_CLOSE_ON_EXIT=FALSE to do so. If you use HSQLDB, you should ensure that shutdown=true is not used. Disabling the database's automatic shutdown lets Spring Boot control when the database is closed, thereby ensuring that it happens once access to the database is no longer needed.

Connection to a Production Database

Production database connections can also be auto-configured by using a pooling DataSource. Spring Boot uses the following algorithm for choosing a specific implementation:

- 1. We prefer <u>HikariCP</u> for its performance and concurrency. If HikariCP is available, we always choose it.
- 2. Otherwise, if the Tomcat pooling ${\tt DataSource}$ is available, we use it.
- 3. If neither HikariCP nor the Tomcat pooling datasource are available and if <u>Commons DBCP2</u> is available, we use it.

If you use the spring-boot-starter-jdbc or spring-boot-starter-data-jpa "starters", you automatically get a dependency to HikariCP.

Note

You can bypass that algorithm completely and specify the connection pool to use by setting the spring.datasource.type property. This is especially important if you run your application in a Tomcat container, as tomcat-jdbc is provided by default.

Tip

Additional connection pools can always be configured manually. If you define your own DataSource bean, auto-configuration does not occur.

DataSource configuration is controlled by external configuration properties in spring.datasource.*. For example, you might declare the following section in application.properties:

```
spring.datasource.url=jdbc:mysql://localhost/test
spring.datasource.username=dbuser
spring.datasource.password=dbpass
spring.datasource.driver-class-name=com.mysql.jdbc.Driver
```

Note

You should at least specify the URL by setting the spring.datasource.url property. Otherwise, Spring Boot tries to auto-configure an embedded database.

You often do not need to specify the driver-class-name, since Spring Boot can deduce it for most databases from the url.

Note

For a pooling DataSource to be created, we need to be able to verify that a valid Driver class is available, so we check for that before doing anything. In other words, if you set spring.datasource.driver-class-name=com.mysql.jdbc.Driver, then that class has to be loadable.

See <u>DataSourceProperties</u> for more of the supported options. These are the standard options that work regardless of the actual implementation. It is also possible to fine-tune implementation-specific settings by using their respective prefix (spring.datasource.hikari.*, spring.datasource.tomcat.*, and spring.datasource.dbcp2.*). Refer to the documentation of the connection pool implementation you are using for more details.

For instance, if you use the <u>Tomcat connection pool</u>, you could customize many additional settings, as shown in the following example:

```
# Number of ms to wait before throwing an exception if no connection is available.
spring.datasource.tomcat.max-wait=10000

# Maximum number of active connections that can be allocated from this pool at the same time.
spring.datasource.tomcat.max-active=50

# Validate the connection before borrowing it from the pool.
spring.datasource.tomcat.test-on-borrow=true
```

Connection to a JNDI DataSource

If you deploy your Spring Boot application to an Application Server, you might want to configure and manage your DataSource by using your Application Server's built-in features and access it by using JNDI.

The spring.datasource.jndi-name property can be used as an alternative to the spring.datasource.url, spring.datasource.username, and spring.datasource.password properties to access the DataSource from a specific JNDI location. For example, the following section in application.properties shows how you can access a JBoss AS defined DataSource:

```
spring.datasource.jndi-name=java:jboss/datasources/customers
```

31.2 Using JdbcTemplate

Spring's JdbcTemplate and NamedParameterJdbcTemplate classes are auto-configured, and you can @Autowire them directly into your own beans, as shown in the following example:

```
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.jdbc.core.JdbcTemplate;
import org.springframework.stereotype.Component;

@Component
public class MyBean {
    private final JdbcTemplate jdbcTemplate;
}
```

```
@Autowired
public MyBean(JdbcTemplate jdbcTemplate) {
  this.jdbcTemplate = jdbcTemplate;
}
// ...
}
```

You can customize some properties of the template by using the spring.jdbc.template.* properties, as shown in the following example:

```
spring.jdbc.template.max-rows=500
```

Note

The NamedParameterJdbcTemplate reuses the same JdbcTemplate instance behind the scenes. If more than one JdbcTemplate is defined and no primary candidate exists, the NamedParameterJdbcTemplate is not auto-configured.

31.3 JPA and "Spring Data"

The Java Persistence API is a standard technology that lets you "map" objects to relational databases. The spring-boot-starter-data-jpa POM provides a quick way to get started. It provides the following key dependencies:

- · Hibernate: One of the most popular JPA implementations.
- Spring Data JPA: Makes it easy to implement JPA-based repositories.
- Spring ORMs: Core ORM support from the Spring Framework.

Tip

We do not go into too many details of JPA or <u>Spring Data</u> here. You can follow the <u>"Accessing Data with JPA"</u> guide from <u>spring.io</u> and read the <u>Spring Data JPA</u> and <u>Hibernate</u> reference documentation.

Entity Classes

Traditionally, JPA "Entity" classes are specified in a persistence.xml file. With Spring Boot, this file is not necessary and "Entity Scanning" is used instead. By default, all packages below your main configuration class (the one annotated with @EnableAutoConfiguration or @SpringBootApplication) are searched.

Any classes annotated with <code>@Entity</code>, <code>@Embeddable</code>, or <code>@MappedSuperclass</code> are considered. A typical entity class resembles the following example:

```
package com.example.myapp.domain;
import java.io.Serializable;
import javax.persistence.*;

@Entity
public class City implements Serializable {
    @Id
    @GeneratedValue
```

```
private Long id;
@Column(nullable = false)
private String name;
@Column(nullable = false)
private String state;
// ... additional members, often include @OneToMany mappings
protected City() {
 // no-args constructor required by JPA spec
 // this one is protected since it shouldn't be used directly
public City(String name, String state) {
 this.name = name;
 this.country = country;
public String getName() {
return this.name;
public String getState() {
 return this.state;
// ... etc
```

You can customize entity scanning locations by using the <code>@EntityScan</code> annotation. See the "Section 80.4, "Separate @Entity Definitions from Spring Configuration"" how-to.

Spring Data JPA Repositories

{http://projects.spring.io/spring-data-jpa/}[Spring Data JPA] repositories are interfaces that you can define to access data. JPA queries are created automatically from your method names. For example, a CityRepository interface might declare a findAllByState(String state) method to find all the cities in a given state.

For more complex queries, you can annotate your method with Spring Data's <u>Query</u> annotation.

Spring Data repositories usually extend from the <u>Repository</u> or <u>CrudRepository</u> interfaces. If you use auto-configuration, repositories are searched from the package containing your main configuration class (the one annotated with @EnableAutoConfiguration or @SpringBootApplication) down.

The following example shows a typical Spring Data repository interface definition:

```
package com.example.myapp.domain;
import org.springframework.data.domain.*;
import org.springframework.data.repository.*;

public interface CityRepository extends Repository<City, Long> {
    Page<City> findAll(Pageable pageable);
    City findByNameAndCountryAllIgnoringCase(String name, String country);
}
```

We have barely scratched the surface of Spring Data JPA. For complete details, see the <u>Spring</u> Data JPA reference documentation.

Creating and Dropping JPA Databases

By default, JPA databases are automatically created **only** if you use an embedded database (H2, HSQL, or Derby). You can explicitly configure JPA settings by using spring.jpa.* properties. For example, to create and drop tables you can add the following line to your application.properties:

 ${\tt spring.jpa.hibernate.ddl-auto=create-drop}$

Note

Hibernate's own internal property name for this (if you happen to remember it better) is hibernate.hbm2ddl.auto. You can set it, along with other Hibernate native properties, by using spring.jpa.properties.* (the prefix is stripped before adding them to the entity manager). The following line shows an example of setting JPA properties for Hibernate:

spring.jpa.properties.hibernate.globally_quoted_identifiers=true

The line in the preceding example passes a value of true for the hibernate.globally_quoted_identifiers property to the Hibernate entity manager.

By default, the DDL execution (or validation) is deferred until the ApplicationContext has started. There is also a spring.jpa.generate-ddl flag, but it is not used if Hibernate auto-configuration is active, because the ddl-auto settings are more fine-grained.

Open EntityManager in View

If you are running a web application, Spring Boot by default registers OpenEntityManagerInViewInterceptor to apply the "Open EntityManager in View" pattern, to allow for lazy loading in web views. If you do not want this behavior, you should set spring. jpa.openin-view to false in your application.properties.

31.4 Using H2's Web Console

The <u>H2 database</u> provides a <u>browser-based console</u> that Spring Boot can auto-configure for you. The console is auto-configured when the following conditions are met:

- You are developing a web application.
- com.h2database:h2 is on the classpath.
- You are using <u>Spring Boot's developer tools</u>.

Tip

If you are not using Spring Boot's developer tools but would still like to make use of H2's console, you can configure the spring.h2.console.enabled property with a value of true.

Note

The H2 console is only intended for use during development, so you should take care to ensure that <code>spring.h2.console.enabled</code> is not set to true in production.

Changing the H2 Console's Path

By default, the console is available at /h2-console. You can customize the console's path by using the spring.h2.console.path property.

31.5 Using jOOQ

Java Object Oriented Querying (jOOQ) is a popular product from <u>Data Geekery</u> which generates Java code from your database and lets you build type-safe SQL queries through its fluent API. Both the commercial and open source editions can be used with Spring Boot.

Code Generation

In order to use jOOQ type-safe queries, you need to generate Java classes from your database schema. You can follow the instructions in the jOOQ user manual. If you use the jooq-codegen-maven plugin and you also use the spring-boot-starter-parent "parent POM", you can safely omit the plugin's <version> tag. You can also use Spring Boot-defined version variables (such as h2.version) to declare the plugin's database dependency. The following listing shows an example:

```
<groupId>org.joog</groupId>
<artifactId>jooq-codegen-maven</artifactId>
<executions>
</executions>
<dependencies>
 <dependency>
  <groupId>com.h2database
  <artifactId>h2</artifactId>
  <version>${h2.version}
 </dependency>
</dependencies>
<configuration>
 <jdbc>
  <driver>org.h2.Driver</driver>
  <url>jdbc:h2:~/yourdatabase</url>
 </jdbc>
 <generator>
 </generator>
</configuration>
</plugin>
```

Using DSLContext

The fluent API offered by jOOQ is initiated through the org.jooq.DSLContext interface. Spring Boot auto-configures a DSLContext as a Spring Bean and connects it to your application DataSource. To use the DSLContext, you can @Autowire it, as shown in the following example:

```
@Component
public class JooqExample implements CommandLineRunner {
    private final DSLContext create;
    @Autowired
```

```
public JooqExample(DSLContext dslContext) {
  this.create = dslContext;
}
```

The jOOQ manual tends to use a variable named create to hold the DSLContext.

You can then use the DSLContext to construct your queries, as shown in the following example:

```
public List<GregorianCalendar> authorsBornAfter1980() {
  return this.create.selectFrom(AUTHOR)
  .where(AUTHOR.DATE_OF_BIRTH.greaterThan(new GregorianCalendar(1980, 0, 1)))
  .fetch(AUTHOR.DATE_OF_BIRTH);
}
```

jOOQ SQL Dialect

Unless the spring.jooq.sql-dialect property has been configured, Spring Boot determines the SQL dialect to use for your datasource. If Spring Boot could not detect the dialect, it uses DEFAULT.

Note

Spring Boot can only auto-configure dialects supported by the open source version of jOOQ.

Customizing jOOQ

More advanced customizations can be achieved by defining your own @Bean definitions, which is used when the jOOQ Configuration is created. You can define beans for the following jOOQ Types:

- ConnectionProvider
- TransactionProvider
- RecordMapperProvider
- RecordListenerProvider
- ExecuteListenerProvider
- VisitListenerProvider

You can also create your own org.jooq.Configuration@Bean if you want to take complete control of the jOOQ configuration.

32. Working with NoSQL Technologies

Spring Data provides additional projects that help you access a variety of NoSQL technologies, including: MongoDB, Neo4J, Elasticsearch, Solr, Redis, Gemfire, Cassandra, Couchbase and LDAP. Spring Boot provides auto-configuration for Redis, MongoDB, Neo4j, Elasticsearch, Solr Cassandra, Couchbase, and LDAP. You can make use of the other projects, but you must configure them yourself. Refer to the appropriate reference documentation at projects.spring.io/spring-data.

32.1 Redis

<u>Redis</u> is a cache, message broker, and richly-featured key-value store. Spring Boot offers basic auto-configuration for the <u>Lettuce</u> and <u>Jedis</u> client libraries and the abstractions on top of them provided by <u>Spring Data Redis</u>.

There is a spring-boot-starter-data-redis "Starter" for collecting the dependencies in a convenient way. By default, it uses <u>Lettuce</u>. That starter handles both traditional and reactive applications.

Tip

we also provide a spring-boot-starter-data-redis-reactive "Starter" for consistency with the other stores with reactive support.

Connecting to Redis

You can inject an auto-configured RedisConnectionFactory, StringRedisTemplate, or vanilla RedisTemplate instance as you would any other Spring Bean. By default, the instance tries to connect to a Redis server at localhost: 6379. The following listing shows an example of such a bean:

```
@Component
public class MyBean {

private StringRedisTemplate template;

@Autowired
public MyBean(StringRedisTemplate template) {
   this.template = template;
}

// ...
}
```

Tip

You can also register an arbitrary number of beans that implement LettuceClientConfigurationBuilderCustomizer for more advanced customizations. If you use Jedis, JedisClientConfigurationBuilderCustomizer is also available.

If you add your own @Bean of any of the auto-configured types, it replaces the default (except in the case of RedisTemplate, when the exclusion is based on the bean name, redisTemplate, not its type). By default, if commons-pool2 is on the classpath, you get a pooled connection factory.

32.2 MongoDB

MongoDB is an open-source NoSQL document database that uses a JSON-like schema instead of traditional table-based relational data. Spring Boot offers several conveniences for working with MongoDB, including the spring-boot-starter-data-mongodb and spring-boot-starter-data-mongodb-reactive "Starters".

Connecting to a MongoDB Database

To access Mongo databases, you can inject an auto-configured org.springframework.data.mongodb.MongoDbFactory. By default, the instance tries to connect to a MongoDB server at mongodb://localhost/test The following example shows how to connect to a MongoDB database:

```
import org.springframework.data.mongodb.MongoDbFactory;
import com.mongodb.DB;

@Component
public class MyBean {
    private final MongoDbFactory mongo;
    @Autowired
    public MyBean(MongoDbFactory mongo) {
        this.mongo = mongo;
    }

// ...
public void example() {
        DB db = mongo.getDb();
        // ...
}
```

You can set the spring.data.mongodb.uri property to change the URL and configure additional settings such as the *replica set*, as shown in the following example:

```
spring.data.mongodb.uri=mongodb://user:secret@mongol.example.com:12345,mongo2.example.com:23456/test
```

Alternatively, as long as you use Mongo 2.x, you can specify a host/port. For example, you might declare the following settings in your application.properties:

```
spring.data.mongodb.host=mongoserver
spring.data.mongodb.port=27017
```

Note

lf Mongo you use the Java driver, spring.data.mongodb.host supported. such spring.data.mongodb.port are not In cases, spring.data.mongodb.uri should be used to provide all of the configuration.

Tip

If spring.data.mongodb.port is not specified, the default of 27017 is used. You could delete this line from the example shown earlier.

If you do not use Spring Data Mongo, you can inject com.mongodb.MongoClient beans instead of using MongoDbFactory. If you want to take complete control of establishing the MongoDB connection, you can also declare your own MongoDbFactory or MongoClient bean.

Note

If you are using the reactive driver, Netty is required for SSL. The auto-configuration configures this factory automatically if Netty is available and the factory to use hasn't been customized already.

MongoTemplate

<u>Spring Data MongoDB</u> provides a <u>MongoTemplate</u> class that is very similar in its design to Spring's JdbcTemplate. As with JdbcTemplate, Spring Boot auto-configures a bean for you to inject the template, as follows:

```
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.data.mongodb.core.MongoTemplate;
import org.springframework.stereotype.Component;

@Component
public class MyBean {
    private final MongoTemplate mongoTemplate;

@Autowired
public MyBean(MongoTemplate mongoTemplate) {
    this.mongoTemplate = mongoTemplate;
}

// ...
}
```

See the MongoOperations Javadoc for complete details.

Spring Data MongoDB Repositories

Spring Data includes repository support for MongoDB. As with the JPA repositories discussed earlier, the basic principle is that queries are constructed automatically, based on method names.

In fact, both Spring Data JPA and Spring Data MongoDB share the same common infrastructure. You could take the JPA example from earlier and, assuming that City is now a Mongo data class rather than a JPA @Entity, it works in the same way, as shown in the following example:

```
package com.example.myapp.domain;
import org.springframework.data.domain.*;
import org.springframework.data.repository.*;

public interface CityRepository extends Repository<City, Long> {
    Page<City> findAll(Pageable pageable);
    City findByNameAndCountryAllIgnoringCase(String name, String country);
}
```

You can customize document scanning locations by using the @EntityScan annotation.

Tip

For complete details of Spring Data MongoDB, including its rich object mapping technologies, refer to its <u>reference documentation</u>.

Embedded Mongo

Spring Boot offers auto-configuration for <u>Embedded Mongo</u>. To use it in your Spring Boot application, add a dependency on de.flapdoodle.embed:de.flapdoodle.embed.mongo.

The port that Mongo listens on can be configured by setting the spring.data.mongodb.port property. To use a randomly allocated free port, use a value of 0. The MongoClient created by MongoAutoConfiguration is automatically configured to use the randomly allocated port.

Note

If you do not configure a custom port, the embedded support uses a random port (rather than 27017) by default.

If you have SLF4J on the classpath, the output produced by Mongo is automatically routed to a logger named org.springframework.boot.autoconfigure.mongo.embedded.EmbeddedMongo.

You can declare your own ${\tt IMongodConfig}$ and ${\tt IRuntimeConfig}$ beans to take control of the Mongo instance's configuration and logging routing.

32.3 Neo4j

Neo4j is an open-source NoSQL graph database that uses a rich data model of nodes related by first class relationships, which is better suited for connected big data than traditional rdbms approaches. Spring Boot offers several conveniences for working with Neo4j, including the spring-boot-starter-data-neo4j "Starter".

Connecting to a Neo4j Database

You can inject an auto-configured Neo4jSession, Session, or Neo4jOperations instance as you would any other Spring Bean. By default, the instance tries to connect to a Neo4j server at localhost:7474. The following example shows how to inject a Neo4j bean:

```
@Component
public class MyBean {

private final Neo4jTemplate neo4jTemplate;

@Autowired
public MyBean(Neo4jTemplate neo4jTemplate) {
    this.neo4jTemplate = neo4jTemplate;
}

// ...
}
```

You can take full control of the configuration by adding a org.neo4j.ogm.config.Configuration @Bean of your own. Also, adding a @Bean of type Neo4jOperations disables the auto-configuration.

You can configure the user and credentials to use by setting the spring.data.neo4j.* properties, as shown in the following example:

```
spring.data.neo4j.uri=http://my-server:7474
spring.data.neo4j.username=neo4j
spring.data.neo4j.password=secret
```

Using the Embedded Mode

If you add org.neo4j:neo4j-ogm-embedded-driver to the dependencies of your application, Spring Boot automatically configures an in-process embedded instance of Neo4j that does not persist any data when your application shuts down. You can explicitly disable that mode by setting spring.data.neo4j.embedded.enabled=false. You can also enable persistence for the embedded mode by providing a path to a database file, as shown in the following example:

```
spring.data.neo4j.uri=file://var/tmp/graph.db
```

Note

The Neo4j OGM embedded driver does not provide the Neo4j kernel. Users are expected to provide this dependency manually. See <u>the documentation</u> for more details.

Neo4jSession

By default, if you are running a web application, the session is bound to the thread for the entire processing of the request (that is, it uses the "Open Session in View" pattern). If you do not want this behavior, add the following line to your application.properties file:

```
spring.data.neo4j.open-in-view=false
```

Spring Data Neo4j Repositories

Spring Data includes repository support for Neo4j.

In fact, both Spring Data JPA and Spring Data Neo4j share the same common infrastructure. You could take the JPA example from earlier and, assuming that City is now a Neo4j OGM @NodeEntity rather than a JPA @Entity, it works in the same way.

Tip

You can customize entity scanning locations by using the @EntityScan annotation.

To enable repository support (and optionally support for @Transactional), add the following two annotations to your Spring configuration:

```
@EnableNeo4jRepositories(basePackages = "com.example.myapp.repository")
@EnableTransactionManagement
```

Repository Example

The following example shows an interface definition for a Neo4j repository:

```
package com.example.myapp.domain;
import org.springframework.data.domain.*;
import org.springframework.data.repository.*;

public interface CityRepository extends GraphRepository<City> {
    Page<City> findAll(Pageable pageable);
    City findByNameAndCountry(String name, String country);
}
```

For complete details of Spring Data Neo4j, including its rich object mapping technologies, refer to the <u>reference documentation</u>.

32.4 Gemfire

Spring Data Gemfire provides convenient Spring-friendly tools for accessing the <u>Pivotal Gemfire</u> data management platform. There is a spring-boot-starter-data-gemfire "Starter" for collecting the dependencies in a convenient way. There is currently no auto-configuration support for Gemfire, but you can enable Spring Data Repositories with a <u>single annotation: @EnableGemfireRepositories</u>.

32.5 Solr

<u>Apache Solr</u> is a search engine. Spring Boot offers basic auto-configuration for the Solr 5 client library and the abstractions on top of it provided by <u>Spring Data Solr</u>. There is a spring-boot-starter-data-solr "Starter" for collecting the dependencies in a convenient way.

Connecting to Solr

You can inject an auto-configured SolrClient instance as you would any other Spring bean. By default, the instance tries to connect to a server at localhost:8983/solr. The following example shows how to inject a Solr bean:

```
@Component
public class MyBean {
    private SolrClient solr;

@Autowired
public MyBean(SolrClient solr) {
    this.solr = solr;
}

// ...
}
```

If you add your own @Bean of type SolrClient, it replaces the default.

Spring Data Solr Repositories

Spring Data includes repository support for Apache Solr. As with the JPA repositories discussed earlier, the basic principle is that queries are automatically constructed for \ you based on method names.

In fact, both Spring Data JPA and Spring Data Solr share the same common infrastructure. You could take the JPA example from earlier and, assuming that City is now a @SolrDocument class rather than a JPA @Entity, it works in the same way.

Tip

For complete details of Spring Data Solr, refer to the reference documentation.

32.6 Elasticsearch

<u>Elasticsearch</u> is an open source, distributed, real-time search and analytics engine. Spring Boot offers basic auto-configuration for Elasticsearch and the abstractions on top of it provided by <u>Spring Data Elasticsearch</u>. There is a spring-boot-starter-data-elasticsearch "Starter" for collecting the dependencies in a convenient way. Spring Boot also supports <u>Jest</u>.

Connecting to Elasticsearch by Using Jest

If you have <code>Jest</code> on the classpath, you can inject an auto-configured <code>JestClient</code> that by default targets <code>localhost:9200</code>. You can further tune how the client is configured, as shown in the following example:

```
spring.elasticsearch.jest.uris=http://search.example.com:9200
spring.elasticsearch.jest.read-timeout=10000
spring.elasticsearch.jest.username=user
spring.elasticsearch.jest.password=secret
```

You can also register an arbitrary number of beans that implement HttpClientConfigBuilderCustomizer for more advanced customizations. The following example tunes additional HTTP settings:

```
static class HttpSettingsCustomizer implements HttpClientConfigBuilderCustomizer {

@Override
public void customize(HttpClientConfig.Builder builder) {
  builder.maxTotalConnection(100).defaultMaxTotalConnectionPerRoute(5);
}
```

To take full control over the registration, define a JestClient bean.

Connecting to Elasticsearch by Using Spring Data

To connect to Elasticsearch, you must provide the address of one or more cluster nodes. The address can be specified by setting the spring.data.elasticsearch.cluster-nodes property to a comma-separated host:port list. With this configuration in place, an ElasticsearchTemplate or TransportClient can be injected like any other Spring bean, as shown in the following example:

```
spring.data.elasticsearch.cluster-nodes=localhost:9300

@Component
public class MyBean {
    private final ElasticsearchTemplate template;
    public MyBean(ElasticsearchTemplate template) {
        this.template = template;
    }
}
```

```
// ...
}
```

If you add your own ElasticsearchTemplate or TransportClient @Bean, it replaces the default.

Spring Data Elasticsearch Repositories

Spring Data includes repository support for Elasticsearch. As with the JPA repositories discussed earlier, the basic principle is that queries are constructed for you automatically based on method names.

In fact, both Spring Data JPA and Spring Data Elasticsearch share the same common infrastructure. You could take the JPA example from earlier and, assuming that City is now an Elasticsearch @Document class rather than a JPA @Entity, it works in the same way.

Tip

For complete details of Spring Data Elasticsearch, refer to the reference documentation.

32.7 Cassandra

<u>Cassandra</u> is an open source, distributed database management system designed to handle large amounts of data across many commodity servers. Spring Boot offers auto-configuration for Cassandra and the abstractions on top of it provided by <u>Spring Data Cassandra</u>. There is a <u>spring-boot-starter-data-cassandra</u> "Starter" for collecting the dependencies in a convenient way.

Connecting to Cassandra

You can inject an auto-configured CassandraTemplate or a Cassandra Session instance as you would with any other Spring Bean. The spring.data.cassandra.* properties can be used to customize the connection. Generally, you provide keyspace-name and contact-points properties, as shown in the following example:

```
spring.data.cassandra.keyspace-name=mykeyspace
spring.data.cassandra.contact-points=cassandrahost1,cassandrahost2
```

The following code listing shows how to inject a Cassandra bean:

```
@Component
public class MyBean {
    private CassandraTemplate template;

@Autowired
public MyBean(CassandraTemplate template) {
    this.template = template;
}

// ...
}
```

If you add your own @Bean of type CassandraTemplate, it replaces the default.

Spring Data Cassandra Repositories

Spring Data includes basic repository support for Cassandra. Currently, this is more limited than the JPA repositories discussed earlier and needs to annotate finder methods with @Query.

For complete details of Spring Data Cassandra, refer to the reference documentation.

32.8 Couchbase

<u>Couchbase</u> is an open-source, distributed, multi-model NoSQL document-oriented database that is optimized for interactive applications. Spring Boot offers auto-configuration for Couchbase and the abstractions on top of it provided by <u>Spring Data Couchbase</u>. There are spring-boot-starter-data-couchbase and spring-boot-starter-data-couchbase-reactive "Starters" for collecting the dependencies in a convenient way.

Connecting to Couchbase

You can get a Bucket and Cluster by adding the Couchbase SDK and some configuration. The spring.couchbase.* properties can be used to customize the connection. Generally, you provide the bootstrap hosts, bucket name, and password, as shown in the following example:

```
spring.couchbase.bootstrap-hosts=my-host-1,192.168.1.123
spring.couchbase.bucket.name=my-bucket
spring.couchbase.bucket.password=secret
```

qiT

You need to provide *at least* the bootstrap host(s), in which case the bucket name is default and the password is an empty String. Alternatively, you can define your own org.springframework.data.couchbase.config.CouchbaseConfigurer @Bean to take control over the whole configuration.

It is also possible to customize some of the CouchbaseEnvironment settings. For instance, the following configuration changes the timeout to use to open a new Bucket and enables SSL support:

```
spring.couchbase.env.timeouts.connect=3000
spring.couchbase.env.ssl.key-store=/location/of/keystore.jks
spring.couchbase.env.ssl.key-store-password=secret
```

Check the spring.couchbase.env.* properties for more details.

Spring Data Couchbase Repositories

Spring Data includes repository support for Couchbase. For complete details of Spring Data Couchbase, refer to the <u>reference documentation</u>.

You can inject an auto-configured CouchbaseTemplate instance as you would with any other Spring Bean, provided a *default* CouchbaseConfigurer is available (which happens when you enable Couchbase support, as explained earlier).

The following examples shows how to inject a Couchbase bean:

```
@Component
public class MyBean {
    private final CouchbaseTemplate template;
    @Autowired
    public MyBean(CouchbaseTemplate template) {
```

```
this.template = template;
}
// ...
}
```

There are a few beans that you can define in your own configuration to override those provided by the auto-configuration:

- A CouchbaseTemplate @Bean with a name of couchbaseTemplate.
- An IndexManager @Bean with a name of couchbaseIndexManager.
- A CustomConversions @Bean with a name of couchbaseCustomConversions.

To avoid hard-coding those names in your own config, you can reuse BeanNames provided by Spring Data Couchbase. For instance, you can customize the converters to use, as follows:

```
@Configuration
public class SomeConfiguration {

@Bean(BeanNames.COUCHBASE_CUSTOM_CONVERSIONS)
public CustomConversions myCustomConversions() {
   return new CustomConversions(...);
}

// ...
}
```

Tip

you want to fully bypass the auto-configuration for Couchbase, implementation Spring Data provide your own of $\verb|org.springframework.data.couchbase.config.AbstractCouchbaseDataConfiguration|.\\$

32.9 LDAP

<u>LDAP</u> (Lightweight Directory Access Protocol) is an open, vendor-neutral, industry standard application protocol for accessing and maintaining distributed directory information services over an IP network. Spring Boot offers auto-configuration for any compliant LDAP server as well as support for the embedded in-memory LDAP server from <u>UnboundID</u>.

LDAP abstractions are provided by <u>Spring Data LDAP</u>. There is a spring-boot-starter-data-ldap "Starter" for collecting the dependencies in a convenient way.

Connecting to an LDAP Server

To connect to an LDAP server, make sure you declare a dependency on the <code>spring-boot-starter-data-ldap</code> "Starter" or <code>spring-ldap-core</code> and then declare the URLs of your server in your application.properties, as shown in the following example:

```
spring.ldap.urls=ldap://myserver:1235
spring.ldap.username=admin
spring.ldap.password=secret
```

If you need to customize connection settings, you can use the spring.ldap.base and spring.ldap.base-environment properties.

Spring Data LDAP Repositories

Spring Data includes repository support for LDAP. For complete details of Spring Data LDAP, refer to the reference documentation.

You can also inject an auto-configured LdapTemplate instance as you would with any other Spring Bean, as shown in the following example:

```
@Component
public class MyBean {
    private final LdapTemplate template;

@Autowired
public MyBean(LdapTemplate template) {
    this.template = template;
}

// ...
}
```

Embedded In-memory LDAP Server

For testing purposes, Spring Boot supports auto-configuration of an in-memory LDAP server from <u>UnboundID</u>. To configure the server, add a dependency to com.unboundid:unboundid-ldapsdk and declare a base-dn property, as follows:

```
spring.ldap.embedded.base-dn=dc=spring,dc=io
```

By default, the server starts on a random port and triggers the regular LDAP support. There is no need to specify a spring.ldap.urls property.

If there is a schema.ldif file on your classpath, it is used to initialize the server. If you want to load the initialization script from a different resource, you can also use the spring.ldap.embedded.ldif property.

By default, a standard schema is used to validate LDIF files. You can turn off validation altogether by setting the spring.ldap.embedded.validation.enabled property. If you have custom attributes, you can use spring.ldap.embedded.validation.schema to define your custom attribute types or object classes.

32.10 InfluxDB

<u>InfluxDB</u> is an open-source time series database optimized for fast, high-availability storage and retrieval of time series data in fields such as operations monitoring, application metrics, Internet-of-Things sensor data, and real-time analytics.

Connecting to InfluxDB

Spring Boot auto-configures an InfluxDB instance, provided the influxdb-java client is on the classpath and the URL of the database is set, as shown in the following example:

```
spring.influx.url=http://172.0.0.1:8086
```

If the connection to InfluxDB requires a user and password, you can set the spring.influx.user and spring.influx.password properties accordingly.

InfluxDB relies on	√OkHttp. If you	ı need to tun	e the http	client	InfluxDB	uses	behind the	scenes,	you
can register an Ok	HttpClient	.Builder b e	ean.						

33. Caching

The Spring Framework provides support for transparently adding caching to an application. At its core, the abstraction applies caching to methods, thus reducing the number of executions based on the information available in the cache. The caching logic is applied transparently, without any interference to the invoker. Spring Boot auto-configures the cache infrastructure as long as caching support is enabled via the <code>@EnableCaching</code> annotation.

Note

Check the <u>relevant section</u> of the Spring Framework reference for more details.

In a nutshell, adding caching to an operation of your service is as easy as adding the relevant annotation to its method, as shown in the following example:

```
import org.springframework.cache.annotation.Cacheable
import org.springframework.stereotype.Component;

@Component
public class MathService {

@Cacheable("piDecimals")
public int computePiDecimal(int i) {
    // ...
}
```

This example demonstrates the use of caching on a potentially costly operation. Before invoking computePiDecimal, the abstraction looks for an entry in the piDecimals cache that matches the i argument. If an entry is found, the content in the cache is immediately returned to the caller, and the method is not invoked. Otherwise, the method is invoked, and the cache is updated before returning the value.

Caution

You can also use the standard JSR-107 (JCache) annotations (such as @CacheResult) transparently. However, we strongly advise you to not mix and match the Spring Cache and JCache annotations.

If you do not add any specific cache library, Spring Boot auto-configures a <u>simple provider</u> that uses concurrent maps in memory. When a cache is required (such as piDecimals in the preceding example), this provider creates it for you. The simple provider is not really recommended for production usage, but it is great for getting started and making sure that you understand the features. When you have made up your mind about the cache provider to use, please make sure to read its documentation to figure out how to configure the caches that your application uses. Nearly all providers require you to explicitly configure every cache that you use in the application. Some offer a way to customize the default caches defined by the spring.cache.cache-names property.

Tip

It is also possible to transparently <u>update</u> or <u>evict</u> data from the cache.

Note

If you use the cache infrastructure with beans that are not interface-based, make sure to enable the proxyTargetClass attribute of @EnableCaching.

33.1 Supported Cache Providers

The cache abstraction does not provide an actual store and relies on abstraction materialized by the org.springframework.cache.Cache and org.springframework.cache.CacheManager interfaces.

If you have not defined a bean of type CacheManager or a CacheResolver named cacheResolver (see CacheManager or a CacheResolver named cacheResolver (see CachingConfigurer), Spring Boot tries to detect the following providers (in the indicated order):

- 1. Generic
- 2. JCache (JSR-107) (EhCache 3, Hazelcast, Infinispan, and others)
- 3. EhCache 2.x
- 4. Hazelcast
- 5. Infinispan
- 6. Couchbase
- 7. Redis
- 8. Caffeine
- 9. Simple

Tip

It is also possible to *force* a particular cache provider by setting the <code>spring.cache.type</code> property. Use this property if you need to <u>disable caching altogether</u> in certain environment (such as tests).

Tip

Use the spring-boot-starter-cache "Starter" to quickly add basic caching dependencies. The starter brings in spring-context-support. If you add dependencies manually, you must include spring-context-support in order to use the JCache, EhCache 2.x, or Guava support.

If the CacheManager is auto-configured by Spring Boot, you can further tune its configuration before it is fully initialized by exposing a bean that implements the CacheManagerCustomizer interface. The following example sets a flag to say that null values should be passed down to the underlying map:

```
@Bean
public CacheManagerCustomizer<ConcurrentMapCacheManager> cacheManagerCustomizer() {
  return new CacheManagerCustomizer<ConcurrentMapCacheManager>() {
   @Override
  public void customize(ConcurrentMapCacheManager cacheManager) {
    cacheManager.setAllowNullValues(false);
  }
};
}
```

Note

In the preceding example, an auto-configured ConcurrentMapCacheManager is expected. If that is not the case (either you provided your own config or a different cache provider was auto-configured), the customizer is not invoked at all. You can have as many customizers as you want, and you can also order them by using @Order or Ordered.

Generic

Generic caching is used if the context defines at least one org.springframework.cache.Cache bean. A CacheManager wrapping all beans of that type is created.

JCache (JSR-107)

<u>JCache</u> is bootstrapped through the presence of a javax.cache.spi.CachingProvider on the classpath (that is, a JSR-107 compliant caching library exists on the classpath), and the JCacheCacheManager is provided by the spring-boot-starter-cache "Starter". Various compliant libraries are available, and Spring Boot provides dependency management for Ehcache 3, Hazelcast, and Infinispan. Any other compliant library can be added as well.

It might happen that more than one provider is present, in which case the provider must be explicitly specified. Even if the JSR-107 standard does not enforce a standardized way to define the location of the configuration file, Spring Boot does its best to accommodate setting a cache with implementation details, as shown in the following example:

```
# Only necessary if more than one provider is present
spring.cache.jcache.provider=com.acme.MyCachingProvider
spring.cache.jcache.config=classpath:acme.xml
```

Note

When a cache library offers both a native implementation and JSR-107 support, Spring Boot prefers the JSR-107 support, so that the same features are available if you switch to a different JSR-107 implementation.

Tip

Spring Boot has general support for Hazelcast. If a single HazelcastInstance is available, it is automatically reused for the CacheManager as well, unless the spring.cache.jcache.config property is specified.

There are two ways to customize the underlying javax.cache.cacheManager:

- Caches can be created on startup by setting the spring.cache.cache-names property. If a custom javax.cache.configuration.Configuration bean is defined, it is used to customize them.
- org.springframework.boot.autoconfigure.cache.JCacheManagerCustomizer beans are invoked with the reference of the CacheManager for full customization.

Tip

If a standard <code>javax.cache.CacheManager</code> bean is defined, it is wrapped automatically in an <code>org.springframework.cache.CacheManager</code> implementation that the abstraction expects. No further customization is applied to it.

EhCache 2.x

EhCache 2.x is used if a file named ehcache.xml can be found at the root of the classpath. If EhCache 2.x is found, the EhCacheCacheManager provided by the spring-boot-starter-cache "Starter" is used to bootstrap the cache manager. An alternate configuration file can be provided as well, as shown in the following example:

```
spring.cache.ehcache.config=classpath:config/another-config.xml
```

Hazelcast

Spring Boot has general support for Hazelcast. If a HazelcastInstance has been auto-configured, it is automatically wrapped in a CacheManager.

Infinispan

<u>Infinispan</u> has no default configuration file location, so it must be specified explicitly. Otherwise, the default bootstrap is used.

```
spring.cache.infinispan.config=infinispan.xml
```

Caches can be created on startup by setting the spring.cache.cache-names property. If a custom ConfigurationBuilder bean is defined, it is used to customize the caches.

Note

The support of Infinispan in Spring Boot is restricted to the embedded mode and is quite basic. If you want more options, you should use the official Infinispan Spring Boot starter instead. See Infinispan's documentation for more details.

Couchbase

If the <u>Couchbase</u> Java client and the <u>couchbase-spring-cache</u> implementation are available and Couchbase is <u>configured</u>, a <u>CouchbaseCacheManager</u> is auto-configured. It is also possible to create additional caches on startup by setting the <u>spring.cache.cache-names</u> property. These caches operate on the <u>Bucket</u> that was auto-configured. You can also create additional caches on another <u>Bucket</u> by using the customizer. Assume you need two caches (cache1 and cache2) on the "main" <u>Bucket</u> and one (cache3) cache with a custom time to live of 2 seconds on the "another" <u>Bucket</u>. You can create the first two caches through configuration, as follows:

```
spring.cache.cache-names=cache1,cache2
```

Then you can define a @Configuration class to configure the extra Bucket and the cache3 cache, as follows:

```
@Configuration
public class CouchbaseCacheConfiguration {

private final Cluster cluster;

public CouchbaseCacheConfiguration(Cluster cluster) {
    this.cluster = cluster;
}

@Bean
public Bucket anotherBucket() {
```

```
return this.cluster.openBucket("another", "secret");
}

@Bean
public CacheManagerCustomizer<CouchbaseCacheManager> cacheManagerCustomizer() {
  return c -> {
    c.prepareCache("cache3", CacheBuilder.newInstance(anotherBucket())
        .withExpiration(2));
  };
};
}
```

This sample configuration reuses the Cluster that was created through auto-configuration.

Redis

If <u>Redis</u> is available and configured, a <u>RedisCacheManager</u> is auto-configured. It is possible to create additional caches on startup by setting the <u>spring.cache.cache-names</u> property and cache defaults can be configured by using <u>spring.cache.redis.*</u> properties. For instance, the following configuration creates <u>cache1</u> and <u>cache2</u> caches with a *time to live* of 10 minutes:

```
spring.cache.cache-names=cache1,cache2
spring.cache.redis.time-to-live=600000
```

Note

By default, a key prefix is added so that, if two separate caches use the same key, Redis does not have overlapping keys and cannot return invalid values. We strongly recommend keeping this setting enabled if you create your own RedisCacheManager.

Tip

You can take full control of the configuration by adding a RedisCacheConfiguration @Bean of your own. This can be useful if you're looking for customizing the serialization strategy.

Caffeine

<u>Caffeine</u> is a Java 8 rewrite of Guava's cache that supersedes support for Guava. If Caffeine is present, a CaffeineCacheManager (provided by the spring-boot-starter-cache "Starter") is auto-configured. Caches can be created on startup by setting the spring.cache.cache-names property and can be customized by one of the following (in the indicated order):

- 1. A cache spec defined by spring.cache.caffeine.spec
- 2. A com.github.benmanes.caffeine.cache.CaffeineSpec bean is defined
- 3. A com.github.benmanes.caffeine.cache.Caffeine bean is defined

For instance, the following configuration creates cache1 and cache2 caches with a maximum size of 500 and a *time to live* of 10 minutes

```
spring.cache.cache-names=cache1,cache2
spring.cache.caffeine.spec=maximumSize=500,expireAfterAccess=600s
```

If a com.github.benmanes.caffeine.cache.CacheLoader bean is defined, it is automatically associated to the CaffeineCacheManager. Since the CacheLoader is going to be associated with

all caches managed by the cache manager, it must be defined as CacheLoader<Object, Object>. The auto-configuration ignores any other generic type.

Simple

If none of the other providers can be found, a simple implementation using a ConcurrentHashMap as the cache store is configured. This is the default if no caching library is present in your application. By default, caches are created as needed, but you can restrict the list of available caches by setting the cache-names property. For instance, if you want only cache1 and cache2 caches, set the cachenames property as follows:

spring.cache.cache-names=cache1,cache2

If you do so and your application uses a cache not listed, then it fails at runtime when the cache is needed, but not on startup. This is similar to the way the "real" cache providers behave if you use an undeclared cache.

None

When @EnableCaching is present in your configuration, a suitable cache configuration is expected as well. If you need to disable caching altogether in certain environments, force the cache type to none to use a no-op implementation, as shown in the following example:

spring.cache.type=none

34. Messaging

The Spring Framework provides extensive support for integrating with messaging systems, from simplified use of the JMS API using <code>JmsTemplate</code> to a complete infrastructure to receive messages asynchronously. Spring AMQP provides a similar feature set for the Advanced Message Queuing Protocol. Spring Boot also provides auto-configuration options for <code>RabbitTemplate</code> and RabbitMQ. Spring WebSocket natively includes support for STOMP messaging, and Spring Boot has support for that through starters and a small amount of auto-configuration. Spring Boot also has support for Apache Kafka.

34.1 JMS

The <code>javax.jms.ConnectionFactory</code> interface provides a standard method of creating a <code>javax.jms.Connection</code> for interacting with a JMS broker. Although Spring needs a <code>ConnectionFactory</code> to work with JMS, you generally need not use it directly yourself and can instead rely on higher level messaging abstractions. (See the <code>relevant section</code> of the Spring Framework reference documentation for details.) Spring Boot also auto-configures the necessary infrastructure to send and receive messages.

ActiveMQ Support

When <u>ActiveMQ</u> is available on the classpath, Spring Boot can also configure a ConnectionFactory. If the broker is present, an embedded broker is automatically started and configured (provided no broker URL is specified through configuration).

Note

If you use spring-boot-starter-activemq, the necessary dependencies to connect or embed an ActiveMQ instance are provided, as is the Spring infrastructure to integrate with JMS.

ActiveMQ configuration is controlled by external configuration properties in spring.activemq.*. For example, you might declare the following section in application.properties:

```
spring.activemq.broker-url=tcp://192.168.1.210:9876
spring.activemq.user=admin
spring.activemq.password=secret
```

You can also pool JMS resources by adding a dependency to org.apache.activemq-pool and configuring the PooledConnectionFactory accordingly, as shown in the following example:

```
spring.activemq.pool.enabled=true
spring.activemq.pool.max-connections=50
```

Tip

See <u>ActiveMQProperties</u> for more of the supported options. You can also register an arbitrary number of beans that implement ActiveMQConnectionFactoryCustomizer for more advanced customizations.

By default, ActiveMQ creates a destination if it does not yet exist so that destinations are resolved against their provided names.

Artemis Support

Spring Boot can auto-configure a ConnectionFactory when it detects that Artemis is available on the classpath. If the broker is present, an embedded broker is automatically started and configured (unless the mode property has been explicitly set). The supported modes are embedded (to make explicit that an embedded broker is required and that an error should occur if the broker is not available on the classpath) and native (to connect to a broker using the netty transport protocol). When the latter is configured, Spring Boot configures a ConnectionFactory that connects to a broker running on the local machine with the default settings.

Note

If you use <code>spring-boot-starter-artemis</code>, the necessary dependencies to connect to an existing Artemis instance are provided, as well as the Spring infrastructure to integrate with JMS. Adding <code>org.apache.activemq:artemis-jms-server</code> to your application lets you use embedded mode.

Artemis configuration is controlled by external configuration properties in spring.artemis.*. For example, you might declare the following section in application.properties:

```
spring.artemis.mode=native
spring.artemis.host=192.168.1.210
spring.artemis.port=9876
spring.artemis.user=admin
spring.artemis.password=secret
```

When embedding the broker, you can choose if you want to enable persistence and list the destinations that should be made available. These can be specified as a commaseparated list to create them with the default options, or you can define bean(s) of type org.apache.activemq.artemis.jms.server.config.JMSQueueConfiguration or org.apache.activemq.artemis.jms.server.config.TopicConfiguration, for advanced queue and topic configurations, respectively.

See ArtemisProperties for more supported options.

No JNDI lookup is involved, and destinations are resolved against their names, using either the name attribute in the Artemis configuration or the names provided through configuration.

Using a JNDI ConnectionFactory

If you are running your application in an application server, Spring Boot tries to locate a JMS ConnectionFactory by using JNDI. By default, the <code>java:/JmsXA</code> and <code>java:/XAConnectionFactory</code> location are checked. You can use the <code>spring.jms.jndi-name</code> property if you need to specify an alternative location, as shown in the following example:

```
spring.jms.jndi-name=java:/MyConnectionFactory
```

Sending a Message

Spring's JmsTemplate is auto-configured, and you can autowire it directly into your own beans, as shown in the following example:

```
import org.springframework.beans.factory.annotation.Autowired;
```

```
import org.springframework.jms.core.JmsTemplate;
import org.springframework.stereotype.Component;

@Component
public class MyBean {
    private final JmsTemplate jmsTemplate;

@Autowired
public MyBean(JmsTemplate jmsTemplate) {
    this.jmsTemplate = jmsTemplate;
}

// ...
}
```

Note

<u>JmsMessagingTemplate</u> can be injected in a similar manner. If a DestinationResolver or a MessageConverter bean is defined, it is associated automatically to the auto-configured JmsTemplate.

Receiving a Message

When the JMS infrastructure is present, any bean can be annotated with @JmsListener to create a listener endpoint. If no JmsListenerContainerFactory has been defined, a default one is configured automatically. If a DestinationResolver or a MessageConverter beans is defined, it is associated automatically to the default factory.

By default, the default factory is transactional. If you run in an infrastructure where a <code>JtaTransactionManager</code> is present, it is associated to the listener container by default. If not, the <code>sessionTransacted</code> flag is enabled. In that latter scenario, you can associate your local data store transaction to the processing of an incoming message by adding <code>@Transactional</code> on your listener method (or a delegate thereof). This ensures that the incoming message is acknowledged, once the local transaction has completed. This also includes sending response messages that have been performed on the same JMS session.

The following component creates a listener endpoint on the someQueue destination:

```
@Component
public class MyBean {

@JmsListener(destination = "someQueue")
public void processMessage(String content) {

// ...
}
```

Tip

See the Javadoc of @EnableJms for more details.

If you need to create more JmsListenerContainerFactory instances or if you want to override the default, Spring Boot provides a DefaultJmsListenerContainerFactoryConfigurer that you can use to initialize a DefaultJmsListenerContainerFactory with the same settings as the one that is auto-configured.

For instance, the following example exposes another factory that uses a specific MessageConverter:

```
@Configuration
static class JmsConfiguration {

@Bean
public DefaultJmsListenerContainerFactory myFactory(
   DefaultJmsListenerContainerFactoryConfigurer configurer) {
   DefaultJmsListenerContainerFactory factory =
        new DefaultJmsListenerContainerFactory();
   configurer.configure(factory, connectionFactory());
   factory.setMessageConverter(myMessageConverter());
   return factory;
}
```

Then you can use the factory in any @JmsListener-annotated method as follows:

```
@Component
public class MyBean {

@JmsListener(destination = "someQueue", containerFactory="myFactory")
public void processMessage(String content) {

// ...
}
```

34.2 AMQP

The Advanced Message Queuing Protocol (AMQP) is a platform-neutral, wire-level protocol for message-oriented middleware. The Spring AMQP project applies core Spring concepts to the development of AMQP-based messaging solutions. Spring Boot offers several conveniences for working with AMQP through RabbitMQ, including the spring-boot-starter-amqp "Starter".

RabbitMQ support

RabbitMQ is a lightweight, reliable, scalable, and portable message broker based on the AMQP protocol. Spring uses RabbitMQ to communicate through the AMQP protocol.

RabbitMQ configuration is controlled by external configuration properties in spring.rabbitmq.*. For example, you might declare the following section in application.properties:

```
spring.rabbitmq.host=localhost
spring.rabbitmq.port=5672
spring.rabbitmq.username=admin
spring.rabbitmq.password=secret
```

See RabbitProperties for more of the supported options.

Tip

See <u>Understanding AMQP</u>, the protocol used by RabbitMQ for more details.

Sending a Message

Spring's AmqpTemplate and AmqpAdmin are auto-configured, and you can autowire them directly into your own beans, as shown in the following example:

```
import org.springframework.amqp.core.AmqpPadmin;
import org.springframework.amqp.core.AmqpTemplate;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.stereotype.Component;

@Component
public class MyBean {
    private final AmqpAdmin amqpAdmin;
    private final AmqpTemplate amqpTemplate;

@Autowired
public MyBean(AmqpAdmin amqpAdmin, AmqpTemplate amqpTemplate) {
    this.amqpAdmin = amqpAdmin;
    this.amqpTemplate = amqpTemplate;
}

// ...
}
```

Note

<u>RabbitMessagingTemplate</u> can be injected in a similar manner. If a MessageConverter bean is defined, it is associated automatically to the auto-configured AmqpTemplate.

If necessary, any org.springframework.amqp.core.Queue that is defined as a bean is automatically used to declare a corresponding queue on the RabbitMQ instance.

To retry operations, you can enable retries on the AmapTemplate (for example, in the event that the broker connection is lost). Retries are disabled by default.

Receiving a Message

When the Rabbit infrastructure is present, any bean can be annotated with @RabbitListener to create a listener endpoint. If no RabbitListenerContainerFactory has been defined, a default SimpleRabbitListenerContainerFactory is automatically configured and you can switch to a direct container using the spring.rabbitmq.listener.type property. If a MessageConverter or a MessageRecoverer bean is defined, it is automatically associated with the default factory.

The following sample component creates a listener endpoint on the someQueue queue:

```
@Component
public class MyBean {

@RabbitListener(queues = "someQueue")
public void processMessage(String content) {

// ...
}
```

Tip

See the Javadoc of @EnableRabbit for more details.

If you need to create more RabbitListenerContainerFactory instances or if you want to override the default, Spring Boot provides a SimpleRabbitListenerContainerFactoryConfigurer and a DirectRabbitListenerContainerFactoryConfigurer that you can use to initialize a SimpleRabbitListenerContainerFactory and a

DirectRabbitListenerContainerFactory with the same settings as the factories used by the auto-configuration.

Tip

It does not matter which container type you chose. Those two beans are exposed by the autoconfiguration.

For instance, the following configuration class exposes another factory that uses a specific MessageConverter:

```
@Configuration
static class RabbitConfiguration {

@Bean
public SimpleRabbitListenerContainerFactory myFactory(
   SimpleRabbitListenerContainerFactoryConfigurer configurer) {
   SimpleRabbitListenerContainerFactory factory =
    new SimpleRabbitListenerContainerFactory();
   configurer.configure(factory, connectionFactory);
   factory.setMessageConverter(myMessageConverter());
   return factory;
}
```

Then you can use the factory in any @RabbitListener-annotated method, as follows:

```
@Component
public class MyBean {

@RabbitListener(queues = "someQueue", containerFactory="myFactory")
public void processMessage(String content) {

// ...
}
```

You can enable retries to handle situations where your listener throws an exception. By default, RejectAndDontRequeueRecoverer is used, but you can define a MessageRecoverer of your own. When retries are exhausted, the message is rejected and either dropped or routed to a dead-letter exchange if the broker is configured to do so. By default, retries are disabled.

Important

By default, if retries are disabled and the listener throws an exception, the delivery is retried indefinitely. You can modify this behavior in two ways: Set the defaultRequeueRejected property to false so that zero re-deliveries are attempted or throw an AmqpRejectAndDontRequeueException to signal the message should be rejected. The latter is the mechanism used when retries are enabled and the maximum number of delivery attempts is reached.

34.3 Apache Kafka Support

Apache Kafka is supported by providing auto-configuration of the spring-kafka project.

Kafka configuration is controlled by external configuration properties in spring.kafka.*. For example, you might declare the following section in application.properties:

```
spring.kafka.bootstrap-servers=localhost:9092
spring.kafka.consumer.group-id=myGroup
```

Tip

To create a topic on startup, add a bean of type NewTopic. If the topic already exists, the bean is ignored.

See $\underline{\mathtt{KafkaProperties}}$ for more supported options.

Sending a Message

Spring's KafkaTemplate is auto-configured, and you can autowire it directly in your own beans, as shown in the following example:

```
@Component
public class MyBean {
    private final KafkaTemplate kafkaTemplate;
    @Autowired
    public MyBean(KafkaTemplate kafkaTemplate) {
        this.kafkaTemplate = kafkaTemplate;
    }
// ...
}
```

Note

If a RecordMessageConverter bean is defined, it is automatically associated to the autoconfigured KafkaTemplate.

Receiving a Message

When the Apache Kafka infrastructure is present, any bean can be annotated with <code>@KafkaListener</code> to create a listener endpoint. If no <code>KafkaListenerContainerFactory</code> has been defined, a default one is automatically configured with keys defined in <code>spring.kafka.listener.*</code>. Also, if a <code>RecordMessageConverter</code> bean is defined, it is automatically associated to the default factory.

The following component creates a listener endpoint on the someTopic topic:

```
@Component
public class MyBean {

@KafkaListener(topics = "someTopic")
public void processMessage(String content) {

/// ...
}
```

Additional Kafka Properties

The properties supported by auto configuration are shown in <u>Appendix A</u>, <u>Common application</u> <u>properties</u>. Note that, for the most part, these properties (hyphenated or camelCase) map directly to the Apache Kafka dotted properties. Refer to the Apache Kafka documentation for details.

The first few of these properties apply to both producers and consumers but can be specified at the producer or consumer level if you wish to use different values for each. Apache Kafka designates properties with an importance of HIGH, MEDIUM, or LOW. Spring Boot auto-configuration supports all HIGH importance properties, some selected MEDIUM and LOW properties, and any properties that do not have a default value.

Only a subset of the properties supported by Kafka are available through the KafkaProperties class. If you wish to configure the producer or consumer with additional properties that are not directly supported, use the following properties:

```
spring.kafka.properties.prop.one=first
spring.kafka.admin.properties.prop.two=second
spring.kafka.consumer.properties.prop.three=third
spring,kafka.producer.properties.prop.four=fourth
```

This sets the common prop.one Kafka property to first (applies to producers, consumers and admins), the prop. two admin property to second, the prop. three consumer property to third and the prop. four producer property to fourth.

You can also configure the Spring Kafka JsonDeserializer as follows:

```
spring.kafka.consumer.value-deserializer=org.springframework.kafka.support.serializer.JsonDeserializer
spring.kafka.consumer.properties.spring.json.value.default.type=org.foo.Invoice
spring.kafka.consumer.properties.spring.json.trusted.packages=org.foo,org.bar
```

Similarly, you can disable the JsonSerializer default behavior of sending type information in headers:

```
spring.kafka.producer.value-serializer=org.springframework.kafka.support.serializer.JsonSerializer
spring.kafka.producer.properties.spring.json.add.type.headers=false
```

Important

Properties set in this way override any configuration item that Spring Boot explicitly supports.

35. Calling REST Services with RestTemplate

If you need to call remote REST services from your application, you can use the Spring Framework's RestTemplate class. Since RestTemplate instances often need to be customized before being used, Spring Boot does not provide any single auto-configured RestTemplate bean. It does, however, auto-configure a RestTemplateBuilder, which can be used to create RestTemplate instances when needed. The auto-configured RestTemplateBuilder ensures that sensible HttpMessageConverters are applied to RestTemplate instances.

The following code shows a typical example:

```
@Service
public class MyService {

private final RestTemplate restTemplate;

public MyBean(RestTemplateBuilder restTemplateBuilder) {
    this.restTemplate = restTemplateBuilder.build();
    }

public Details someRestCall(String name) {
    return this.restTemplate.getForObject("/{name}/details", Details.class, name);
}
```

Tip

RestTemplateBuilder includes a number of useful methods that can be used to quickly configure a RestTemplate. For example, to add BASIC auth support, you can use builder.basicAuthorization("user", "password").build().

35.1 RestTemplate Customization

There are three main approaches to RestTemplate customization, depending on how broadly you want the customizations to apply.

To make the scope of any customizations as narrow as possible, inject the auto-configured RestTemplateBuilder and then call its methods as required. Each method call returns a new RestTemplateBuilder instance, so the customizations only affect this use of the builder.

To make an application-wide, additive customization, use a RestTemplateCustomizer bean. All such beans are automatically registered with the auto-configured RestTemplateBuilder and are applied to any templates that are built with it.

The following example shows a customizer that configures the use of a proxy for all hosts except 192.168.0.5:

```
static class ProxyCustomizer implements RestTemplateCustomizer {

@Override
public void customize(RestTemplate restTemplate) {
   HttpHost proxy = new HttpHost("proxy.example.com");
   HttpClient httpClient = HttpClientBuilder.create()
        .setRoutePlanner(new DefaultProxyRoutePlanner(proxy) {

        @Override
        public HttpHost determineProxy(HttpHost target,
```

```
HttpRequest request, HttpContext context)
          throws HttpException {
    if (target.getHostName().equals("192.168.0.5")) {
        return null;
    }
    return super.determineProxy(target, request, context);
}

}).build();
restTemplate.setRequestFactory(
    new HttpComponentsClientHttpRequestFactory(httpClient));
}
```

Finally, the most extreme (and rarely used) option is to create your own RestTemplateBuilder bean. Doing so switches off the auto-configuration of a RestTemplateBuilder and prevents any RestTemplateCustomizer beans from being used.

36. Calling REST Services with WebClient

If you have Spring WebFlux on your classpath, you can also choose to use <code>WebClient</code> to call remote REST services. Compared to <code>RestTemplate</code>, this client has a more functional feel and is fully reactive. You can create your own client instance with the builder, <code>WebClient.create()</code>. See the <code>relevant</code> section on <code>WebClient</code>.

Spring Boot creates and pre-configures such a builder for you. For example, client HTTP codecs are configured in the same fashion as the server ones (see WebFlux HTTP codecs auto-configuration).

The following code shows a typical example:

36.1 WebClient Customization

There are three main approaches to WebClient customization, depending on how broadly you want the customizations to apply.

To make the scope of any customizations as narrow as possible, inject the auto-configured WebClient.Builder and then call its methods as required. WebClient.Builder instances are stateful: Any change on the builder is reflected in all clients subsequently created with it. If you want to create several clients with the same builder, you can also consider cloning the builder with WebClient.Builder other = builder.clone();

To make an application-wide, additive customization to all WebClient.Builder instances, you can declare WebClientCustomizer beans and change the WebClient.Builder locally at the point of injection.

Finally, you can fall back to the original API and use <code>WebClient.create()</code>. In that case, no autoconfiguration or <code>WebClientCustomizer</code> is applied.

37. Validation

The method validation feature supported by Bean Validation 1.1 is automatically enabled as long as a JSR-303 implementation (such as Hibernate validator) is on the classpath. This lets bean methods be annotated with <code>javax.validation</code> constraints on their parameters and/or on their return value. Target classes with such annotated methods need to be annotated with the <code>@Validated</code> annotation at the type level for their methods to be searched for inline constraint annotations.

For instance, the following service triggers the validation of the first argument, making sure its size is between 8 and 10:

```
@Service
@Validated
public class MyBean {

public Archive findByCodeAndAuthor(@Size(min = 8, max = 10) String code,
   Author author) {
   ...
}
```

38. Sending Email

The Spring Framework provides an easy abstraction for sending email by using the JavaMailSender interface, and Spring Boot provides auto-configuration for it as well as a starter module.

Tip

See the <u>reference documentation</u> for a detailed explanation of how you can use JavaMailSender.

If spring.mail.host and the relevant libraries (as defined by spring-boot-starter-mail) are available, a default JavaMailSender is created if none exists. The sender can be further customized by configuration items from the spring.mail namespace. See MailProperties for more details.

In particular, certain default timeout values are infinite, and you may want to change that to avoid having a thread blocked by an unresponsive mail server, as shown in the following example:

```
spring.mail.properties.mail.smtp.connectiontimeout=5000
spring.mail.properties.mail.smtp.timeout=3000
spring.mail.properties.mail.smtp.writetimeout=5000
```

39. Distributed Transactions with JTA

Spring Boot supports distributed JTA transactions across multiple XA resources by using either an Atomikos or Bitronix embedded transaction manager. JTA transactions are also supported when deploying to a suitable Java EE Application Server.

When a JTA environment is detected, Spring's JtaTransactionManager is used to manage transactions. Auto-configured JMS, DataSource, and JPA beans are upgraded to support XA transactions. You can use standard Spring idioms, such as @Transactional, to participate in a distributed transaction. If you are within a JTA environment and still want to use local transactions, you can set the spring.jta.enabled property to false to disable the JTA auto-configuration.

39.1 Using an Atomikos Transaction Manager

Atomikos is a popular open source transaction manager which can be embedded into your Spring Boot application. You can use the <code>spring-boot-starter-jta-atomikos</code> Starter to pull in the appropriate Atomikos libraries. Spring Boot auto-configures Atomikos and ensures that appropriate <code>depends-on</code> settings are applied to your Spring beans for correct startup and shutdown ordering.

By default, Atomikos transaction logs are written to a transaction-logs directory in your application's home directory (the directory in which your application jar file resides). You can customize the location of this directory by setting a spring.jta.log-dir property in your application.properties file. Properties starting with spring.jta.atomikos.properties can also be used to customize the Atomikos UserTransactionServiceImp. See the AtomikosProperties Javadoc for complete details.

Note

To ensure that multiple transaction managers can safely coordinate the same resource managers, each Atomikos instance must be configured with a unique ID. By default, this ID is the IP address of the machine on which Atomikos is running. To ensure uniqueness in production, you should configure the <code>spring.jta.transaction-manager-id</code> property with a different value for each instance of your application.

39.2 Using a Bitronix Transaction Manager

<u>Bitronix</u> is a popular open-source JTA transaction manager implementation. You can use the spring-boot-starter-jta-bitronix starter to add the appropriate Bitronix dependencies to your project. As with Atomikos, Spring Boot automatically configures Bitronix and post-processes your beans to ensure that startup and shutdown ordering is correct.

By default, Bitronix transaction log files (part1.btm and part2.btm) are written to a transaction-logs directory in your application home directory. You can customize the location of this directory by setting the spring.jta.log-dir property. Properties starting with spring.jta.bitronix.properties are also bound to the bitronix.tm.Configuration bean, allowing for complete customization. See the <u>Bitronix documentation</u> for details.

Note

To ensure that multiple transaction managers can safely coordinate the same resource managers, each Bitronix instance must be configured with a unique ID. By default, this ID is the IP address

of the machine on which Bitronix is running. To ensure uniqueness in production, you should configure the spring.jta.transaction-manager-id property with a different value for each instance of your application.

39.3 Using a Narayana Transaction Manager

Narayana is a popular open source JTA transaction manager implementation supported by JBoss. You can use the spring-boot-starter-jta-narayana starter to add the appropriate Narayana dependencies to your project. As with Atomikos and Bitronix, Spring Boot automatically configures Narayana and post-processes your beans to ensure that startup and shutdown ordering is correct.

By default, Narayana transaction logs are written to a transaction-logs directory in your application home directory (the directory in which your application jar file resides). You can customize the location of this directory by setting a spring.jta.log-dir property in your application.properties file. Properties starting with spring.jta.narayana.properties can also be used to customize the Narayana configuration. See the NarayanaProperties Javadoc for complete details.

Note

To ensure that multiple transaction managers can safely coordinate the same resource managers, each Narayana instance must be configured with a unique ID. By default, this ID is set to 1. To ensure uniqueness in production, you should configure the spring.jta.transaction—manager-id property with a different value for each instance of your application.

39.4 Using a Java EE Managed Transaction Manager

If you package your Spring Boot application as a war or ear file and deploy it to a Java EE application server, you can use your application server's built-in transaction manager. Spring Boot tries to auto-configure a transaction manager by looking at common JNDI locations (java:comp/UserTransaction, java:comp/TransactionManager, and so on). If you use a transaction service provided by your application server, you generally also want to ensure that all resources are managed by the server and exposed over JNDI. Spring Boot tries to auto-configure JMS by looking for a ConnectionFactory at the JNDI path (java:/JmsXA or java:/XAConnectionFactory), and you can use the spring.datasource.jndi-name property to configure your DataSource.

39.5 Mixing XA and Non-XA JMS Connections

When using JTA, the primary JMS ConnectionFactory bean is XA-aware and participates in distributed transactions. In some situations, you might want to process certain JMS messages by using a non-XA ConnectionFactory. For example, your JMS processing logic might take longer than the XA timeout.

If you want to use a non-XA ConnectionFactory, you can inject the nonXaJmsConnectionFactory bean rather than the @Primary jmsConnectionFactory bean. For consistency, the jmsConnectionFactory bean is also provided by using the bean alias xaJmsConnectionFactory.

The following example shows how to inject ConnectionFactory instances:

```
// Inject the primary (XA aware) ConnectionFactory
@Autowired
private ConnectionFactory defaultConnectionFactory;
```

```
// Inject the XA aware ConnectionFactory (uses the alias and injects the same as above)
@Autowired
@Qualifier("xaJmsConnectionFactory")
private ConnectionFactory xaConnectionFactory;

// Inject the non-XA aware ConnectionFactory
@Autowired
@Qualifier("nonXaJmsConnectionFactory")
private ConnectionFactory nonXaConnectionFactory;
```

39.6 Supporting an Alternative Embedded Transaction Manager

The XAConnectionFactoryWrapper and XADataSourceWrapper interfaces can be used to support alternative embedded transaction managers. The interfaces are responsible for wrapping XAConnectionFactory and XADataSource beans and exposing them as regular ConnectionFactory and DataSource beans, which transparently enroll in the distributed transaction. DataSource and JMS auto-configuration use JTA variants, provided you have a JtaTransactionManager bean and appropriate XA wrapper beans registered within your ApplicationContext.

The <u>BitronixXAConnectionFactoryWrapper</u> and <u>BitronixXADataSourceWrapper</u> provide good examples of how to write XA wrappers.

40. Hazelcast

If <u>Hazelcast</u> is on the classpath and a suitable configuration is found, Spring Boot auto-configures a HazelcastInstance that you can inject in your application.

If you define a com.hazelcast.config.Config bean, Spring Boot uses that. If your configuration defines an instance name, Spring Boot tries to locate an existing instance rather than creating a new one.

You could also specify the hazelcast.xml configuration file to use through configuration, as shown in the following example:

```
spring.hazelcast.config=classpath:config/my-hazelcast.xml
```

Otherwise, Spring Boot tries to find the Hazelcast configuration from the default locations: hazelcast.xml in the working directory or at the root of the classpath. We also check if the hazelcast.config system property is set. See the <u>Hazelcast documentation</u> for more details.

If hazelcast-client is present on the classpath, Spring Boot first attempts to create a client by checking the following configuration options:

- The presence of a com.hazelcast.client.config.ClientConfig bean.
- A configuration file defined by the spring.hazelcast.config property.
- The presence of the hazelcast.client.config system property.
- A hazelcast-client.xml in the working directory or at the root of the classpath.

Note

Spring Boot also has <u>explicit caching support for Hazelcast</u>. If caching is enabled, the HazelcastInstance is automatically wrapped in a CacheManager implementation.

41. Quartz Scheduler

Spring Boot offers several conveniences for working with the <u>Quartz scheduler</u>, including the spring-boot-starter-quartz "Starter". If Quartz is available, a Scheduler is auto-configured (through the SchedulerFactoryBean abstraction).

Beans of the following types are automatically picked up and associated with the Scheduler:

- JobDetail: defines a particular Job. JobDetail instances can be built with the JobBuilder API.
- Calendar.
- Trigger: defines when a particular job is triggered.

By default, an in-memory JobStore is used. However, it is possible to configure a JDBC-based store if a DataSource bean is available in your application and if the spring.quartz.job-store-type property is configured accordingly, as shown in the following example:

```
spring.quartz.job-store-type=jdbc
```

When the JDBC store is used, the schema can be initialized on startup, as shown in the following example:

```
spring.quartz.jdbc.initialize-schema=always
```

Note

By default, the database is detected and initialized by using the standard scripts provided with the Quartz library. It is also possible to provide a custom script by setting the spring.quartz.jdbc.schema property.

Quartz Scheduler configuration can be customized by using Quartz configuration properties ()spring.quartz.properties.*) and SchedulerFactoryBeanCustomizer beans, which allow programmatic SchedulerFactoryBean customization.

Jobs can define setters to inject data map properties. Regular beans can also be injected in a similar manner, as shown in the following example:

42. Spring Integration

Spring Boot offers several conveniences for working with <u>Spring Integration</u>, including the <u>spring-boot-starter-integration</u> "Starter". Spring Integration provides abstractions over messaging and also other transports such as HTTP, TCP, and others. If Spring Integration is available on your classpath, it is initialized through the <code>@EnableIntegration</code> annotation.

Spring Boot also configures some features that are triggered by the presence of additional Spring Integration modules. If <code>spring-integration-jmx</code> is also on the classpath, message processing statistics are published over JMX . If <code>spring-integration-jdbc</code> is available, the default database schema can be created on startup, as shown in the following line:

spring.integration.jdbc.initialize-schema=always

See the <u>IntegrationAutoConfiguration</u> and <u>IntegrationProperties</u> classes for more details.

43. Spring Session

Spring Boot provides <u>Spring Session</u> auto-configuration for a wide range of data stores. When building a Servlet web application, the following stores can be auto-configured:

- JDBC
- Redis
- Hazelcast
- MongoDB

When building a reactive web application, the following stores can be auto-configured:

- Redis
- MongoDB

If Spring Session is available, you must choose the <u>StoreType</u> that you wish to use to store the sessions. For instance, to use JDBC as the back-end store, you can configure your application as follows:

spring.session.store-type=jdbc

Tip

You can disable Spring Session by setting the store-type to none.

Each store has specific additional settings. For instance, it is possible to customize the name of the table for the JDBC store, as shown in the following example:

spring.session.jdbc.table-name=SESSIONS

44. Monitoring and Management over JMX

Java Management Extensions (JMX) provide a standard mechanism to monitor and manage applications. By default, Spring Boot creates an MBeanServer bean with an ID of mbeanServer and exposes any of your beans that are annotated with Spring JMX annotations (@ManagedResource, @ManagedAttribute, or @ManagedOperation).

See the <u>JmxAutoConfiguration</u> class for more details.

45. Testing

Spring Boot provides a number of utilities and annotations to help when testing your application. Test support is provided by two modules: spring-boot-test contains core items, and spring-boot-test-autoconfigure supports auto-configuration for tests.

Most developers use the spring-boot-starter-test "Starter", which imports both Spring Boot test modules as well as JUnit, AssertJ, Hamcrest, and a number of other useful libraries.

45.1 Test Scope Dependencies

The spring-boot-starter-test "Starter" (in the test scope)contains the following provided libraries:

- JUnit: The de-facto standard for unit testing Java applications.
- Spring Test & Spring Boot Test: Utilities and integration test support for Spring Boot applications.
- AssertJ: A fluent assertion library.
- <u>Hamcrest</u>: A library of matcher objects (also known as constraints or predicates).
- Mockito: A Java mocking framework.
- JSONassert: An assertion library for JSON.
- JsonPath: XPath for JSON.

We generally find these common libraries to be useful when writing tests. If these libraries do not suit your needs, you can add additional test dependencies of your own.

45.2 Testing Spring Applications

One of the major advantages of dependency injection is that it should make your code easier to unit test. You can instantiate objects by using the new operator without even involving Spring. You can also use *mock objects* instead of real dependencies.

Often, you need to move beyond unit testing and start integration testing (with a Spring ApplicationContext). It is useful to be able to perform integration testing without requiring deployment of your application or needing to connect to other infrastructure.

The Spring Framework includes a dedicated test module for such integration testing. You can declare a dependency directly to org.springframework:spring-test or use the spring-boot-starter-test "Starter" to pull it in transitively.

If you have not used the spring-test module before, you should start by reading the <u>relevant section</u> of the Spring Framework reference documentation.

45.3 Testing Spring Boot Applications

A Spring Boot application is a Spring ApplicationContext, so nothing very special has to be done to test it beyond what you would normally do with a vanilla Spring context.

Note

External properties, logging, and other features of Spring Boot are installed in the context by default only if you use SpringApplication to create it.

Spring Boot provides a @SpringBootTest annotation, which can be used as an alternative to the standard spring-test @ContextConfiguration annotation when you need Spring Boot features. The annotation works by creating the ApplicationContext used in your tests through SpringApplication.

You can use the webEnvironment attribute of @SpringBootTest to further refine how your tests run:

- MOCK: Loads a WebApplicationContext and provides a mock servlet environment. Embedded
 servlet containers are not started when using this annotation. If servlet APIs are not on your classpath,
 this mode transparently falls back to creating a regular non-web ApplicationContext. It can be
 used in conjunction with @AutoConfigureMockMvc for MockMvc-based testing of your application.
- RANDOM_PORT: Loads an ServletWebServerApplicationContext and provides a real servlet environment. Embedded servlet containers are started and listen on a random port.
- DEFINED_PORT: Loads a ServletWebServerApplicationContext and provides a real servlet environment. Embedded servlet containers are started and listen on a defined port (from your application.properties or on the default port of 8080).
- NONE: Loads an ApplicationContext by using SpringApplication but does not provide any servlet environment (mock or otherwise).

Note

If your test is @Transactional, it rolls back the transaction at the end of each test method by default. However, as using this arrangement with either RANDOM_PORT or DEFINED_PORT implicitly provides a real servlet environment, the HTTP client and server run in separate threads and, thus, in separate transactions. Any transaction initiated on the server does not roll back in this case.

Note

In addition to @SpringBootTest, a number of other annotations are also provided for testing more specific slices of an application. You can find more detail throughout this chapter.

Tip

Do not forget to add @RunWith(SpringRunner.class) to your test. Otherwise, the annotations are ignored.

Detecting Test Configuration

If you are familiar with the Spring Test Framework, you may be used to using <code>@ContextConfiguration(classes=...)</code> in order to specify which Spring <code>@Configuration</code> to load. Alternatively, you might have often used nested <code>@Configuration</code> classes within your test.

When testing Spring Boot applications, this is often not required. Spring Boot's @*Test annotations search for your primary configuration automatically whenever you do not explicitly define one.

The search algorithm works up from the package that contains the test until it finds a class annotated with @SpringBootApplication or @SpringBootConfiguration. As long as you structured your code in a sensible way, your main configuration is usually found.

Note

If you use a <u>test annotation to test a more specific slice of your application</u>, you should avoid adding configuration settings that are specific to a particular area on the <u>main method's application class</u>.

If you want to customize the primary configuration, you can use a nested @TestConfiguration class. Unlike a nested @Configuration class, which would be used instead of your application's primary configuration, a nested @TestConfiguration class is used in addition to your application's primary configuration.

Note

Spring's test framework caches application contexts between tests. Therefore, as long as your tests share the same configuration (no matter how it is discovered), the potentially time-consuming process of loading the context happens only once.

Excluding Test Configuration

If your application uses component scanning (for example, if you use @SpringBootApplication or @ComponentScan), you may find top-level configuration classes that you created only for specific tests accidentally get picked up everywhere.

As we <u>have seen earlier</u>, @TestConfiguration can be used on an inner class of a test to customize the primary configuration. When placed on a top-level class, @TestConfiguration indicates that classes in src/test/java should not be picked up by scanning. You can then import that class explicitly where it is required, as shown in the following example:

```
@RunWith(SpringRunner.class)
@SpringBootTest
@Import(MyTestsConfiguration.class)
public class MyTests {
    @Test
    public void exampleTest() {
        ...
    }
}
```

Note

If you directly use <code>@ComponentScan</code> (that is, not through <code>@SpringBootApplication</code>) you need to register the <code>TypeExcludeFilter</code> with it. See the Javadoc for details.

Working with Random Ports

If you need to start a full running server for tests, we recommend that you use random ports. If you use @SpringBootTest(webEnvironment=WebEnvironment.RANDOM_PORT), an available port is picked at random each time your test runs.

The @LocalServerPort annotation can be used to <u>inject the actual port used</u> into your test. For convenience, tests that need to make REST calls to the started server can additionally @Autowire a TestRestTemplate, which resolves relative links to the running server, as shown in the following example:

```
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.context.SpringBootTest;
import org.springframework.boot.test.context.SpringBootTest.WebEnvironment;
import org.springframework.boot.test.web.client.TestRestTemplate;
import org.springframework.test.context.junit4.SpringRunner;
import static org.assertj.core.api.Assertions.assertThat;
@RunWith(SpringRunner.class)
@SpringBootTest(webEnvironment = WebEnvironment.RANDOM_PORT)
public class RandomPortTestRestTemplateExampleTests {
@Autowired
private TestRestTemplate restTemplate;
@Test
public void exampleTest() {
 String body = this.restTemplate.getForObject("/", String.class);
 assertThat(body).isEqualTo("Hello World");
```

If you prefer to use a WebTestClient, you can use that as well:

```
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.context.SpringBootTest;
import org.springframework.boot.test.context.SpringBootTest.WebEnvironment;
import org.springframework.test.context.junit4.SpringRunner;
import org.springframework.test.web.reactive.server.WebTestClient;
@RunWith(SpringRunner.class)
@SpringBootTest(webEnvironment = WebEnvironment.RANDOM_PORT)
public class RandomPortWebTestClientExampleTests {
@Autowired
private WebTestClient webClient;
public void exampleTest() {
 this.webClient.get()
   .uri("/")
   .exchange()
   .expectStatus().isOk()
   .expectBody(String.class).isEqualTo("Hello World");
}
```

Mocking and Spying Beans

When running tests, it is sometimes necessary to mock certain components within your application context. For example, you may have a facade over some remote service that is unavailable during development. Mocking can also be useful when you want to simulate failures that might be hard to trigger in a real environment.

Spring Boot includes a <code>@MockBean</code> annotation that can be used to define a Mockito mock for a bean inside your <code>ApplicationContext</code>. You can use the annotation to add new beans or replace a single existing bean definition. The annotation can be used directly on test classes, on fields within your test, or on <code>@Configuration</code> classes and fields. When used on a field, the instance of the created mock is also injected. Mock beans are automatically reset after each test method.

Note

If your test uses one of Spring Boot's test annotations (such as @SpringBootTest), this feature is automatically enabled. To use this feature with a different arrangement, a listener must be explicitly added, as shown in the following example:

```
@TestExecutionListeners(MockitoTestExecutionListener.class)
```

The following example replaces an existing RemoteService bean with a mock implementation:

```
import org.junit.*;
import org.junit.runner.*;
import org.springframework.beans.factory.annotation.*;
import org.springframework.boot.test.context.*;
import org.springframework.boot.test.mock.mockito.*;
import org.springframework.test.context.junit4.*;
import static org.assertj.core.api.Assertions.*;
import static org.mockito.BDDMockito.*;
@RunWith(SpringRunner.class)
@SpringBootTest
public class MyTests {
@MockBean
private RemoteService remoteService;
@Autowired
private Reverser reverser;
public void exampleTest() {
 // RemoteService has been injected into the reverser bean
 given(this.remoteService.someCall()).willReturn("mock");
 String reverse = reverser.reverseSomeCall();
 assertThat(reverse).isEqualTo("kcom");
```

Additionally, you can use @SpyBean to wrap any existing bean with a Mockito spy. See the <u>Javadoc</u> for full details.

Auto-configured Tests

Spring Boot's auto-configuration system works well for applications but can sometimes be a little too much for tests. It often helps to load only the parts of the configuration that are required to test a "slice" of your application. For example, you might want to test that Spring MVC controllers are mapping URLs correctly, and you do not want to involve database calls in those tests, or you might want to test JPA entities, and you are not interested in the web layer when those tests run.

The spring-boot-test-autoconfigure module includes a number of annotations that can be used to automatically configure such "slices". Each of them works in a similar way, providing a @...Test

annotation that loads the ApplicationContext and one or more @AutoConfigure... annotations that can be used to customize auto-configuration settings.

Note

Each slice loads a very restricted set of auto-configuration classes. If you need to exclude one of them, most @...Test annotations provide an excludeAutoConfiguration attribute. Alternatively, you can use @ImportAutoConfiguration#exclude.

Tip

It is also possible to use the <code>@AutoConfigure...</code> annotations with the standard <code>@SpringBootTest</code> annotation. You can use this combination if you are not interested in "slicing" your application but you want some of the auto-configured test beans.

Auto-configured JSON Tests

To test that object JSON serialization and deserialization is working as expected, you can use the <code>@JsonTest</code> annotation. <code>@JsonTest</code> auto-configures the available supported JSON mapper, which can be one of the following libraries:

- Jackson ObjectMapper, any @JsonComponent beans and any Jackson Modules
- Gson
- Jsonb

If you need to configure elements of the auto-configuration, you can use the @AutoConfigureJsonTesters annotation.

Spring Boot includes AssertJ-based helpers that work with the JSONassert and JsonPath libraries to check that JSON appears as expected. The <code>JacksonTester</code>, <code>GsonTester</code>, <code>JsonbTester</code>, and <code>BasicJsonTester</code> classes can be used for Jackson, Gson, Jsonb, and Strings respectively. Any helper fields on the test class can be <code>@Autowired</code> when using <code>@JsonTest</code>. The following example shows a test class for Jackson:

```
import org.junit.*;
import org.junit.runner.*;
import org.springframework.beans.factory.annotation.*;
import org.springframework.boot.test.autoconfigure.json.*;
import org.springframework.boot.test.context.*;
import org.springframework.boot.test.json.*;
import org.springframework.test.context.junit4.*;
import static org.assertj.core.api.Assertions.*;
@RunWith(SpringRunner.class)
@JsonTest.
public class MyJsonTests {
@Autowired
private JacksonTester<VehicleDetails> json;
public void testSerialize() throws Exception {
 VehicleDetails details = new VehicleDetails("Honda", "Civic");
 // Assert against a `.json` file in the same package as the test
 assertThat(this.json.write(details)).isEqualToJson("expected.json");
// Or use JSON path based assertions
```

```
assertThat(this.json.write(details)).hasJsonPathStringValue("@.make");
assertThat(this.json.write(details)).extractingJsonPathStringValue("@.make")
    .isEqualTo("Honda");
}

@Test
public void testDeserialize() throws Exception {
    String content = "{\"make\":\"Ford\",\"model\":\"Focus\"}";
    assertThat(this.json.parse(content))
    .isEqualTo(new VehicleDetails("Ford", "Focus"));
    assertThat(this.json.parseObject(content).getMake()).isEqualTo("Ford");
}
```

Note

JSON helper classes can also be used directly in standard unit tests. To do so, call the initFields method of the helper in your @Before method if you do not use @JsonTest.

A list of the auto-configuration that is enabled by @JsonTest can be found in the appendix.

Auto-configured Spring MVC Tests

To test whether Spring MVC controllers are working as expected, use the <code>@WebMvcTest</code> annotation. <code>@WebMvcTest</code> auto-configures the Spring MVC infrastructure and limits scanned beans to <code>@Controller</code>, <code>@Controller</code>Advice, <code>@JsonComponent</code>, <code>Converter</code>, <code>GenericConverter</code>, <code>Filter</code>, <code>WebMvcConfigurer</code>, and <code>HandlerMethodArgumentResolver</code>. Regular <code>@Component</code> beans are not scanned when using this annotation.

Tip

If you need to register extra components, such as the Jackson Module, you can import additional configuration classes by using @Import on your test.

Often, @WebMvcTest is limited to a single controller and is used in combination with @MockBean to provide mock implementations for required collaborators.

@WebMvcTest also auto-configures MockMvc. Mock MVC offers a powerful way to quickly test MVC controllers without needing to start a full HTTP server.

Tip

You can also auto-configure MockMvc in a non-@WebMvcTest (such as @SpringBootTest) by annotating it with @AutoConfigureMockMvc. The following example uses MockMvc:

```
import org.junit.*;
import org.junit.runner.*;
import org.springframework.beans.factory.annotation.*;
import org.springframework.boot.test.autoconfigure.web.servlet.*;
import org.springframework.boot.test.mock.mockito.*;

import static org.assertj.core.api.Assertions.*;
import static org.mockito.BDDMockito.*;
import static org.springframework.test.web.servlet.request.MockMvcRequestBuilders.*;
import static org.springframework.test.web.servlet.result.MockMvcResultMatchers.*;
```

```
@WebMvcTest(UserVehicleController.class)
public class MyControllerTests {

@Autowired
private MockMvc mvc;

@MockBean
private UserVehicleService userVehicleService;

@Test
public void testExample() throws Exception {
    given(this.userVehicleService.getVehicleDetails("sboot"))
    .willReturn(new VehicleDetails("Honda", "Civic"));
    this.mvc.perform(get("/sboot/vehicle").accept(MediaType.TEXT_PLAIN))
    .andExpect(status().isOk()).andExpect(content().string("Honda Civic"));
}
```

Tip

If you need to configure elements of the auto-configuration (for example, when servlet filters should be applied) you can use attributes in the <code>@AutoConfigureMockMvc</code> annotation.

If you use HtmlUnit or Selenium, auto-configuration also provides an HTMLUnit WebClient bean and/ or a WebDriver bean. The following example uses HtmlUnit:

```
import com.gargoylesoftware.htmlunit.*;
import org.junit.*;
import org.junit.runner.*;
import org.springframework.beans.factory.annotation.*;
import org.springframework.boot.test.autoconfigure.web.servlet.*;
import org.springframework.boot.test.mock.mockito.*;
import static org.assertj.core.api.Assertions.*;
import static org.mockito.BDDMockito.*;
@RunWith(SpringRunner.class)
@WebMvcTest(UserVehicleController.class)
public class MyHtmlUnitTests {
@Autowired
private WebClient webClient;
@MockBean
private UserVehicleService userVehicleService;
 public void testExample() throws Exception {
 given(this.userVehicleService.getVehicleDetails("sboot"))
    .willReturn(new VehicleDetails("Honda", "Civic"));
 HtmlPage page = this.webClient.getPage("/sboot/vehicle.html");
 assertThat(page.getBody().getTextContent()).isEqualTo("Honda Civic");
```

Note

By default, Spring Boot puts WebDriver beans in a special "scope" to ensure that the driver exits after each test and that a new instance is injected. If you do not want this behavior, you can add @Scope("singleton") to your WebDriver @Bean definition.

A list of the auto-configuration settings that are enabled by @WebMvcTest can be found in the appendix.

Auto-configured Spring WebFlux Tests

To test that <u>Spring WebFlux</u> controllers are working as expected, you can use the @WebFluxTest annotation. @WebFluxTest auto-configures the Spring WebFlux infrastructure and limits scanned beans to @Controller, @ControllerAdvice, @JsonComponent, Converter, GenericConverter, and WebFluxConfigurer. Regular @Component beans are not scanned when the @WebFluxTest annotation is used.

Tip

If you need to register extra components, such as Jackson Module, you can import additional configuration classes using @Import on your test.

Often, @WebFluxTest is limited to a single controller and used in combination with the @MockBean annotation to provide mock implementations for required collaborators.

@WebFluxTest also auto-configures <u>WebTestClient</u>WebTestClient, which offers a powerful way to quickly test WebFlux controllers without needing to start a full HTTP server.

Tip

You can also auto-configure WebTestClient in a non-@WebFluxTest (such as @SpringBootTest) by annotating it with @AutoConfigureWebTestClient. The following example shows a class that uses both @WebFluxTest and a WebTestClient:

```
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.autoconfigure.web.reactive.WebFluxTest;
import org.springframework.http.MediaType;
import org.springframework.test.context.junit4.SpringRunner;
import org.springframework.test.web.reactive.server.WebTestClient;
@RunWith(SpringRunner.class)
@WebFluxTest(UserVehicleController.class)
public class MyControllerTests {
private WebTestClient webClient;
@MockBean
private UserVehicleService userVehicleService;
public void testExample() throws Exception {
 given(this.userVehicleService.getVehicleDetails("sboot"))
    .willReturn(new VehicleDetails("Honda", "Civic"));
 this.webClient.get().uri("/sboot/vehicle").accept(MediaType.TEXT_PLAIN)
   .exchange()
   .expectStatus().isOk()
    .expectBody(String.class).isEqualTo("Honda Civic");
 }
```

A list of the auto-configuration that is enabled by @WebFluxTest can be found in the appendix.

Auto-configured Data JPA Tests

You can use the @DataJpaTest annotation to test JPA applications. By default, it configures an inmemory embedded database, scans for @Entity classes, and configures Spring Data JPA repositories. Regular @Component beans are not loaded into the ApplicationContext.

By default, data JPA tests are transactional and roll back at the end of each test. See the <u>relevant section</u> in the Spring Framework Reference Documentation for more details. If that is not what you want, you can disable transaction management for a test or for the whole class as follows:

```
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.boot.test.autoconfigure.orm.jpa.DataJpaTest;
import org.springframework.test.context.junit4.SpringRunner;
import org.springframework.transaction.annotation.Propagation;
import org.springframework.transaction.annotation.Transactional;

@RunWith(SpringRunner.class)
@DataJpaTest
@Transactional(propagation = Propagation.NOT_SUPPORTED)
public class ExampleNonTransactionalTests {
}
```

Data JPA tests may also inject a <u>TestEntityManager</u> bean, which provides an alternative to the standard JPA EntityManager that is specifically designed for tests. If you want to use <u>TestEntityManager</u> outside of <code>@DataJpaTest</code> instances, you can also use the <code>@AutoConfigureTestEntityManager</code> annotation. A JdbcTemplate is also available if you need that. The following example shows the <code>@DataJpaTest</code> annotation in use:

```
import org.junit.*;
import org.junit.runner.*;
import org.springframework.boot.test.autoconfigure.orm.jpa.*;
import static org.assertj.core.api.Assertions.*;
@RunWith(SpringRunner.class)
@DataJpaTest
public class ExampleRepositoryTests {
@Autowired
private TestEntityManager entityManager;
private UserRepository repository;
public void testExample() throws Exception {
 this.entityManager.persist(new User("sboot", "1234"));
 User user = this.repository.findByUsername("sboot");
 assertThat(user.getUsername()).isEqualTo("sboot");
 assertThat(user.getVin()).isEqualTo("1234");
}
```

In-memory embedded databases generally work well for tests, since they are fast and do not require any installation. If, however, you prefer to run tests against a real database you can use the <code>@AutoConfigureTestDatabase</code> annotation, as shown in the following example:

```
@RunWith(SpringRunner.class)
@DataJpaTest
@AutoConfigureTestDatabase(replace=Replace.NONE)
public class ExampleRepositoryTests {
```

```
// ...
}
```

A list of the auto-configuration settings that are enabled by @DataJpaTest can be found in the appendix.

Auto-configured JDBC Tests

@JdbcTest is similar to @DataJpaTest but is for pure JDBC-related tests. By default, it also configures an in-memory embedded database and a JdbcTemplate. Regular @Component beans are not loaded into the ApplicationContext.

By default, JDBC tests are transactional and roll back at the end of each test. See the <u>relevant section</u> in the Spring Framework Reference Documentation for more details. If that is not what you want, you can disable transaction management for a test or for the whole class, as follows:

```
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.boot.test.autoconfigure.jdbc.JdbcTest;
import org.springframework.test.context.junit4.SpringRunner;
import org.springframework.transaction.annotation.Propagation;
import org.springframework.transaction.annotation.Transactional;

@RunWith(SpringRunner.class)
@JdbcTest
@Transactional(propagation = Propagation.NOT_SUPPORTED)
public class ExampleNonTransactionalTests {
}
```

If you prefer your test to run against a real database, you can use the <code>@AutoConfigureTestDatabase</code> annotation in the same way as for <code>DataJpaTest</code>. (See "the section called "Auto-configured Data JPA Tests".)

A list of the auto-configuration that is enabled by @JdbcTest can be found in the appendix.

Auto-configured jOOQ Tests

You can use @JooqTest in a similar fashion as @JdbcTest but for jOOQ-related tests. As jOOQ relies heavily on a Java-based schema that corresponds with the database schema, the existing DataSource is used. If you want to replace it with an in-memory database, you can use @AutoconfigureTestDatabase to override those settings. (For more about using jOOQ with Spring Boot, see "Section 31.5, "Using jOOQ"", earlier in this chapter.)

@JooqTest configures a DSLContext. Regular @Component beans are not loaded into the ApplicationContext. The following example shows the @JooqTest annotation in use:

```
import org.jooq.DSLContext;
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.boot.test.autoconfigure.jooq.JooqTest;
import org.springframework.test.context.junit4.SpringRunner;

@RunWith(SpringRunner.class)
@JooqTest
public class ExampleJooqTests {

@Autowired
```

```
private DSLContext dslContext;
}
```

JOOQ tests are transactional and roll back at the end of each test by default. If that is not what you want, you can disable transaction management for a test or for the whole test class as <u>shown in the JDBC example</u>.

A list of the auto-configuration that is enabled by @JooqTest can be found in the appendix.

Auto-configured Data MongoDB Tests

You can use @DataMongoTest to test MongoDB applications. By default, it configures an in-memory embedded MongoDB (if available), configures a MongoTemplate, scans for @Document classes, and configures Spring Data MongoDB repositories. Regular @Component beans are not loaded into the ApplicationContext. (For more about using MongoDB with Spring Boot, see "Section 32.2, "MongoDB"", earlier in this chapter.)

The following class shows the @DataMongoTest annotation in use:

```
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.autoconfigure.data.mongo.DataMongoTest;
import org.springframework.data.mongodb.core.MongoTemplate;
import org.springframework.test.context.junit4.SpringRunner;

@RunWith(SpringRunner.class)
@DataMongoTest
public class ExampleDataMongoTests {

@Autowired
private MongoTemplate mongoTemplate;

///
}
```

In-memory embedded MongoDB generally works well for tests, since it is fast and does not require any developer installation. If, however, you prefer to run tests against a real MongoDB server, you should exclude the embedded MongoDB auto-configuration, as shown in the following example:

```
import org.junit.runner.RunWith;
import org.springframework.boot.autoconfigure.mongo.embedded.EmbeddedMongoAutoConfiguration;
import org.springframework.boot.test.autoconfigure.data.mongo.DataMongoTest;
import org.springframework.test.context.junit4.SpringRunner;

@RunWith(SpringRunner.class)
@DataMongoTest(excludeAutoConfiguration = EmbeddedMongoAutoConfiguration.class)
public class ExampleDataMongoNonEmbeddedTests {
}
```

A list of the auto-configuration settings that are enabled by @DataMongoTest can be found in the appendix.

Auto-configured Data Neo4j Tests

You can use @DataNeo4jTest to test Neo4j applications. By default, it uses an in-memory embedded Neo4j (if the embedded driver is available), scans for @NodeEntity classes, and configures Spring Data Neo4j repositories. Regular @Component beans are not loaded into the ApplicationContext. (For more about using Neo4J with Spring Boot, see "Section 32.3, "Neo4j", earlier in this chapter.)

The following example shows a typical setup for using Neo4J tests in Spring Boot:

```
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.autoconfigure.data.neo4j.DataNeo4jTest;
import org.springframework.test.context.junit4.SpringRunner;

@RunWith(SpringRunner.class)
@DataNeo4jTest
public class ExampleDataNeo4jTests {

@Autowired
private YourRepository repository;

///
}
```

By default, Data Neo4j tests are transactional and roll back at the end of each test. See the <u>relevant section</u> in the Spring Framework Reference Documentation for more details. If that is not what you want, you can disable transaction management for a test or for the whole class, as follows:

```
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.boot.test.autoconfigure.data.neo4j.DataNeo4jTest;
import org.springframework.test.context.junit4.SpringRunner;
import org.springframework.transaction.annotation.Propagation;
import org.springframework.transaction.annotation.Transactional;

@RunWith(SpringRunner.class)
@DataNeo4jTest
@Transactional(propagation = Propagation.NOT_SUPPORTED)
public class ExampleNonTransactionalTests {
}
```

A list of the auto-configuration settings that are enabled by @DataNeo4jTest can be found in the appendix.

Auto-configured Data Redis Tests

You can use @DataRedisTest to test Redis applications. By default, it scans for @RedisHash classes and configures Spring Data Redis repositories. Regular @Component beans are not loaded into the ApplicationContext. (For more about using Redis with Spring Boot, see "Section 32.1, "Redis", earlier in this chapter.)

The following example shows the @DataRedisTest annotation in use:

```
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.autoconfigure.data.redis.DataRedisTest;
import org.springframework.test.context.junit4.SpringRunner;

@RunWith(SpringRunner.class)
@DataRedisTest
public class ExampleDataRedisTests {

@Autowired
private YourRepository repository;

///
}
```

A list of the auto-configuration settings that are enabled by @DataRedisTest can be found in the appendix.

Auto-configured Data LDAP Tests

You can use <code>@DataLdapTest</code> to test LDAP applications. By default, it configures an in-memory embedded LDAP (if available), configures an <code>LdapTemplate</code>, scans for <code>@Entry</code> classes, and configures Spring Data LDAP repositories. Regular <code>@Component</code> beans are not loaded into the <code>ApplicationContext</code>. (For more about using LDAP with Spring Boot, see "Section 32.9, "LDAP", earlier in this chapter.)

The following example shows the @DataLdapTest annotation in use:

```
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.autoconfigure.data.ldap.DataLdapTest;
import org.springframework.ldap.core.LdapTemplate;
import org.springframework.test.context.junit4.SpringRunner;

@RunWith(SpringRunner.class)
@DataLdapTest
public class ExampleDataLdapTests {

@Autowired
private LdapTemplate ldapTemplate;

///
}
```

In-memory embedded LDAP generally works well for tests, since it is fast and does not require any developer installation. If, however, you prefer to run tests against a real LDAP server, you should exclude the embedded LDAP auto-configuration, as shown in the following example:

```
import org.junit.runner.RunWith;
import org.springframework.boot.autoconfigure.ldap.embedded.EmbeddedLdapAutoConfiguration;
import org.springframework.boot.test.autoconfigure.data.ldap.DataLdapTest;
import org.springframework.test.context.junit4.SpringRunner;

@RunWith(SpringRunner.class)
@DataLdapTest(excludeAutoConfiguration = EmbeddedLdapAutoConfiguration.class)
public class ExampleDataLdapNonEmbeddedTests {
}
```

A list of the auto-configuration settings that are enabled by @DataLdapTest can be found in the appendix.

Auto-configured REST Clients

You can use the @RestClientTest annotation to test REST clients. By default, it auto-configures Jackson, GSON, and Jsonb support, configures a RestTemplateBuilder, and adds support for MockRestServiceServer. The specific beans that you want to test should be specified by using the value or components attribute of @RestClientTest, as shown in the following example:

```
@RunWith(SpringRunner.class)
@RestClientTest(RemoteVehicleDetailsService.class)
public class ExampleRestClientTest {

@Autowired
private RemoteVehicleDetailsService service;

@Autowired
private MockRestServiceServer server;

@Test
```

```
public void getVehicleDetailsWhenResultIsSuccessShouldReturnDetails()
    throws Exception {
    this.server.expect(requestTo("/greet/details"))
        .andRespond(withSuccess("hello", MediaType.TEXT_PLAIN));
    String greeting = this.service.callRestService();
    assertThat(greeting).isEqualTo("hello");
}
```

A list of the auto-configuration settings that are enabled by @RestClientTest can be found in the appendix.

Auto-configured Spring REST Docs Tests

You can use the @AutoConfigureRestDocs annotation to use <u>Spring REST Docs</u> in your tests with Mock MVC or REST Assured. It removes the need for the JUnit rule in Spring REST Docs.

@AutoConfigureRestDocs can be used to override the default output directory (target/generated-snippets if you are using Maven or build/generated-snippets if you are using Gradle). It can also be used to configure the host, scheme, and port that appears in any documented URIs.

Auto-configured Spring REST Docs Tests with Mock MVC

@AutoConfigureRestDocs customizes the MockMvc bean to use Spring REST Docs. You can inject it by using @Autowired and use it in your tests as you normally would when using Mock MVC and Spring REST Docs, as shown in the following example:

```
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.autoconfigure.web.servlet.WebMvcTest;
import org.springframework.http.MediaType;
import org.springframework.test.context.junit4.SpringRunner;
import org.springframework.test.web.servlet.MockMvc;
import static org.springframework.restdocs.mockmvc.MockMvcRestDocumentation.document;
import static org.springframework.test.web.servlet.request.MockMvcRequestBuilders.get;
import static org.springframework.test.web.servlet.result.MockMvcResultMatchers.*;
@RunWith(SpringRunner.class)
@WebMvcTest(UserController.class)
@AutoConfigureRestDocs
public class UserDocumentationTests {
@Autowired
private MockMvc mvc;
public void listUsers() throws Exception {
 this.mvc.perform(get("/users").accept(MediaType.TEXT_PLAIN))
   .andExpect(status().isOk())
    .andDo(document("list-users"));
}
```

If you require more control over Spring REST Docs configuration than offered by the attributes of @AutoConfigureRestDocs, you can use a RestDocsMockMvcConfigurationCustomizer bean, as shown in the following example:

```
@TestConfiguration
static class CustomizationConfiguration
  implements RestDocsMockMvcConfigurationCustomizer {

@Override
  public void customize(MockMvcRestDocumentationConfigurer configurer) {
    configurer.snippets().withTemplateFormat(TemplateFormats.markdown());
  }
}
```

If you want to make use of Spring REST Docs support for a parameterized output directory, you can create a RestDocumentationResultHandler bean. The auto-configuration calls alwaysDo with this result handler, thereby causing each MockMvc call to automatically generate the default snippets. The following example shows a RestDocumentationResultHandler being defined:

```
@TestConfiguration
static class ResultHandlerConfiguration {

@Bean
public RestDocumentationResultHandler restDocumentation() {
   return MockMvcRestDocumentation.document("{method-name}");
}
```

Auto-configured Spring REST Docs Tests with REST Assured

@AutoConfigureRestDocs makes a RequestSpecification bean, preconfigured to use Spring REST Docs, available to your tests. You can inject it by using @Autowired and use it in your tests as you normally would when using REST Assured and Spring REST Docs, as shown in the following example:

```
import io.restassured.specification.RequestSpecification;
import org.junit.Test;
import org.junit.runner.RunWith;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.test.autoconfigure.restdocs.AutoConfigureRestDocs;
import org.springframework.boot.test.context.SpringBootTest;
import org.springframework.boot.test.context.SpringBootTest.WebEnvironment;
import org.springframework.boot.web.server.LocalServerPort;
import org.springframework.test.context.junit4.SpringRunner;
import static io.restassured.RestAssured.given;
import static org.hamcrest.CoreMatchers.is;
import static org.springframework.restdocs.restassured3.RestAssuredRestDocumentation.document;
@RunWith(SpringRunner.class)
@SpringBootTest(webEnvironment = WebEnvironment.RANDOM_PORT)
@AutoConfigureRestDocs
public class UserDocumentationTests {
@LocalServerPort
private int port;
@Autowired
private RequestSpecification documentationSpec;
@Test
public void listUsers() {
 given(this.documentationSpec).filter(document("list-users")).when()
    .port(this.port).get("/").then().assertThat().statusCode(is(200));
}
```

If you require more control over Spring REST Docs configuration than offered by the attributes of @AutoConfigureRestDocs, a RestDocsRestAssuredConfigurationCustomizer bean can be used, as shown in the following example:

```
@TestConfiguration
public static class CustomizationConfiguration
  implements RestDocsRestAssuredConfigurationCustomizer {

@Override
public void customize(RestAssuredRestDocumentationConfigurer configurer) {
  configurer.snippets().withTemplateFormat(TemplateFormats.markdown());
  }
}
```

User Configuration and Slicing

If you <u>structure your code</u> in a sensible way, your @SpringBootApplication class is <u>used by default</u> as the configuration of your tests.

It then becomes important not to litter the application's main class with configuration settings that are specific to a particular area of its functionality.

Assume that you are using Spring Batch and you rely on the auto-configuration for it. You could define your @SpringBootApplication as follows:

```
@SpringBootApplication
@EnableBatchProcessing
public class SampleApplication { ... }
```

Because this class is the source configuration for the test, any slice test actually tries to start Spring Batch, which is definitely not what you want to do. A recommended approach is to move that area-specific configuration to a separate @Configuration class at the same level as your application, as shown in the following example:

```
@Configuration
@EnableBatchProcessing
public class BatchConfiguration { ... }
```

Note

Depending on the complexity of your application, you may either have a single @Configuration class for your customizations or one class per domain area. The latter approach lets you enable it in one of your tests, if necessary, with the @Import annotation.

Another source of confusion is classpath scanning. Assume that, while you structured your code in a sensible way, you need to scan an additional package. Your application may resemble the following code:

```
@SpringBootApplication
@ComponentScan({ "com.example.app", "org.acme.another" })
public class SampleApplication { ... }
```

Doing so effectively overrides the default component scan directive with the side effect of scanning those two packages regardless of the slice that you chose. For instance, a @DataJpaTest seems to suddenly scan components and user configurations of your application. Again, moving the custom directive to a separate class is a good way to fix this issue.

Tip

If this is not an option for you, you can create a @SpringBootConfiguration somewhere in the hierarchy of your test so that it is used instead. Alternatively, you can specify a source for your test, which disables the behavior of finding a default one.

Using Spock to Test Spring Boot Applications

If you wish to use Spock to test a Spring Boot application, you should add a dependency on Spock's spock-spring module to your application's build. spock-spring integrates Spring's test framework into Spock. It is recommended that you use Spock 1.1 or later to benefit from a number of improvements to Spock's Spring Framework and Spring Boot integration. See the documentation for Spock's Spring module for further details.

45.4 Test Utilities

A few test utility classes that are generally useful when testing your application are packaged as part of spring-boot.

ConfigFileApplicationContextInitializer

ConfigFileApplicationContextInitializer is an ApplicationContextInitializer that you can apply to your tests to load Spring Boot application.properties files. You can use it when you do not need the full set of features provided by @SpringBootTest, as shown in the following example:

```
@ContextConfiguration(classes = Config.class,
initializers = ConfigFileApplicationContextInitializer.class)
```

Note

Using ConfigFileApplicationContextInitializer alone does not provide support for @Value("\${...}") injection. Its only job is to ensure that application.properties files are loaded into Spring's Environment. For @Value support, you need to either additionally configure a PropertySourcesPlaceholderConfigurer or use @SpringBootTest, which auto-configures one for you.

EnvironmentTestUtils

EnvironmentTestUtils lets you quickly add properties to a ConfigurableEnvironment or ConfigurableApplicationContext. You can call it with key=value strings, as follows:

```
EnvironmentTestUtils.addEnvironment(env, "org=Spring", "name=Boot");
```

OutputCapture

OutputCapture is a JUnit Rule that you can use to capture System.out and System.err output. You can declare the capture as a @Rule and then use toString() for assertions, as follows:

```
import org.junit.Rule;
import org.junit.Test;
import org.springframework.boot.test.rule.OutputCapture;
import static org.hamcrest.Matchers.*;
```

```
import static org.junit.Assert.*;

public class MyTest {

@Rule
  public OutputCapture capture = new OutputCapture();

@Test
  public void testName() throws Exception {
    System.out.println("Hello World!");
    assertThat(capture.toString(), containsString("World"));
  }
}
```

TestRestTemplate

TestRestTemplate is a convenience alternative to Spring's RestTemplate that is useful in integration tests. You can get a vanilla template or one that sends Basic HTTP authentication (with a username and password). In either case, the template behaves in a test-friendly way by not throwing exceptions on server-side errors. It is recommended, but not mandatory, to use the Apache HTTP Client (version 4.3.2 or better). If you have that on your classpath, the TestRestTemplate responds by configuring the client appropriately. If you do use Apache's HTTP client, some additional test-friendly features are enabled:

- Redirects are not followed (so you can assert the response location).
- Cookies are ignored (so the template is stateless).

TestRestTemplate can be instantiated directly in your integration tests, as shown in the following example:

```
public class MyTest {
    private TestRestTemplate template = new TestRestTemplate();
    @Test
    public void testRequest() throws Exception {
        HttpHeaders headers = template.getForEntity("http://myhost.com/example", String.class).getHeaders();
        assertThat(headers.getLocation().toString(), containsString("myotherhost"));
    }
}
```

Alternatively, if you use the @SpringBootTest annotation with WebEnvironment.RANDOM_PORT or WebEnvironment.DEFINED_PORT, you can inject a fully configured TestRestTemplate and start using it. If necessary, additional customizations can be applied through the RestTemplateBuilder bean. Any URLs that do not specify a host and port automatically connect to the embedded server, as shown in the following example:

```
@RunWith(SpringRunner.class)
@SpringBootTest
public class MyTest {

@Autowired
private TestRestTemplate template;

@Test
public void testRequest() throws Exception {
   HttpHeaders headers = template.getForEntity("/example", String.class).getHeaders();
   assertThat(headers.getLocation().toString(), containsString("myotherhost"));
}
```

```
@TestConfiguration
static class Config {

@Bean
public RestTemplateBuilder restTemplateBuilder() {
  return new RestTemplateBuilder()
    .additionalMessageConverters(...)
    .customizers(...);
}
```

46. WebSockets

Spring Boot provides WebSockets auto-configuration for embedded Tomcat 8.5, Jetty 9, and Undertow. If you deploy a war file to a standalone container, Spring Boot assumes that the container is responsible for the configuration of its WebSocket support.

Spring Framework provides <u>rich WebSocket support</u> that can be easily accessed through the spring-boot-starter-websocket module.

47. Web Services

Spring Boot provides Web Services auto-configuration so that all you must do is define your Endpoints.

The <u>Spring Web Services features</u> can be easily accessed with the spring-boot-starter-webservices module.

SimpleWsdl11Definition and SimpleXsdSchema beans can be automatically created for your WSDLs and XSDs respectively. To do so, configure their location, as shown in the following example:

spring.webservices.wsdl-locations=classpath:/wsdl

48. Creating Your Own Auto-configuration

If you work in a company that develops shared libraries, or if you work on an open-source or commercial library, you might want to develop your own auto-configuration. Auto-configuration classes can be bundled in external jars and still be picked-up by Spring Boot.

Auto-configuration can be associated to a "starter" that provides the auto-configuration code as well as the typical libraries that you would use with it. We first cover what you need to know to build your own auto-configuration and then we move on to the <u>typical steps required to create a custom starter</u>.

Tip

A <u>demo project</u> is available to showcase how you can create a starter step-by-step.

48.1 Understanding Auto-configured Beans

Under the hood, auto-configuration is implemented with standard @Configuration classes. Additional @Conditional annotations are used to constrain when the auto-configuration should apply. Usually, auto-configuration classes use @ConditionalOnClass and @ConditionalOnMissingBean annotations. This ensures that auto-configuration applies only when relevant classes are found and when you have not declared your own @Configuration.

You can browse the source code of spring-boot-autoconfigure to see the @Configuration classes that Spring provides (see the META-INF/spring.factories file).

48.2 Locating Auto-configuration Candidates

Spring Boot checks for the presence of a META-INF/spring.factories file within your published jar. The file should list your configuration classes under the EnableAutoConfiguration key, as shown in the following example:

```
org.springframework.boot.autoconfigure.EnableAutoConfiguration=\
com.mycorp.libx.autoconfigure.LibXAutoConfiguration,\
com.mycorp.libx.autoconfigure.LibXWebAutoConfiguration
```

You can use the <u>@AutoConfigureAfter</u> or <u>@AutoConfigureBefore</u> annotations if your configuration needs to be applied in a specific order. For example, if you provide web-specific configuration, your class may need to be applied after WebMvcAutoConfiguration.

If you want to order certain auto-configurations that should not have any direct knowledge of each other, you can also use <code>@AutoConfigureOrder</code>. That annotation has the same semantic as the regular <code>@Order</code> annotation but provides a dedicated order for auto-configuration classes.

Note

Auto-configurations must be loaded that way *only*. Make sure that they are defined in a specific package space and that, in particular, they are never the target of component scanning.

48.3 Condition Annotations

You almost always want to include one or more @Conditional annotations on your auto-configuration class. The @ConditionalOnMissingBean annotation is one common example that is used to allow developers to override auto-configuration if they are not happy with your defaults.

Spring Boot includes a number of @Conditional annotations that you can reuse in your own code by annotating @Configuration classes or individual @Bean methods. These annotations include:

- · the section called "Class Conditions"
- · the section called "Bean Conditions"
- the section called "Property Conditions"
- the section called "Resource Conditions"
- the section called "Web Application Conditions"
- the section called "SpEL Expression Conditions"

Class Conditions

The @ConditionalOnClass and @ConditionalOnMissingClass annotations let configuration be included based on the presence or absence of specific classes. Due to the fact that annotation metadata is parsed by using <u>ASM</u>, you can use the value attribute to refer to the real class, even though that class might not actually appear on the running application classpath. You can also use the name attribute if you prefer to specify the class name by using a String value.

Tip

If you use <code>@ConditionalOnClass</code> or <code>@ConditionalOnMissingClass</code> as a part of a meta-annotation to compose your own composed annotations, you must use <code>name</code> as referring to the class in such a case is not handled.

Bean Conditions

The @ConditionalOnBean and @ConditionalOnMissingBean annotations let a bean be included based on the presence or absence of specific beans. You can use the value attribute to specify beans by type or name to specify beans by name. The search attribute lets you limit the ApplicationContext hierarchy that should be considered when searching for beans.

When placed on a @Bean method, the target type defaults to the return type of the method, as shown in the following example:

```
@Configuration
public class MyAutoConfiguration {

@Bean
@ConditionalOnMissingBean
public MyService myService() { ... }
}
```

In the preceding example, the myService bean is going to be created if no bean of type MyService is already contained in the ApplicationContext.

Tip

You need to be very careful about the order in which bean definitions are added, as these conditions are evaluated based on what has been processed so far. For this reason, we recommend using only @ConditionalOnBean and @ConditionalOnMissingBean

annotations on auto-configuration classes (since these are guaranteed to load after any userdefined bean definitions have been added).

Note

@ConditionalOnBean and @ConditionalOnMissingBean do not prevent @Configuration classes from being created. Using these conditions at the class level is equivalent to marking each contained @Bean method with the annotation.

Property Conditions

The <code>@ConditionalOnProperty</code> annotation lets configuration be included based on a Spring Environment property. Use the <code>prefix</code> and <code>name</code> attributes to specify the property that should be checked. By default, any property that exists and is not equal to <code>false</code> is matched. You can also create more advanced checks by using the <code>havingValue</code> and <code>matchlfMissing</code> attributes.

Resource Conditions

The <code>@ConditionalOnResource</code> annotation lets configuration be included only when a specific resource is present. Resources can be specified by using the usual Spring conventions, as shown in the following example: file:/home/user/test.dat.

Web Application Conditions

The @ConditionalOnWebApplication and @ConditionalOnNotWebApplication annotations let configuration be included depending on whether the application is a "web application". A web application is any application that uses a Spring WebApplicationContext, defines a session scope, or has a StandardServletEnvironment.

SpEL Expression Conditions

The @ConditionalOnExpression annotation lets configuration be included based on the result of a <u>SpEL expression</u>.

48.4 Testing your Auto-configuration

An auto-configuration can be affected by many factors: user configuration (@Bean definition and Environment customization), condition evaluation (presence of a particular library), and others. Concretely, each test should create a well defined ApplicationContext that represents a combination of those customizations. ApplicationContextRunner provides a great way to achieve that.

ApplicationContextRunner is usually defined as a field of the test class to gather the base, common configuration. The following example makes sure that <code>UserServiceAutoConfiguration</code> is always invoked:

```
private final ApplicationContextRunner contextRunner = new ApplicationContextRunner()
.withConfiguration(AutoConfigurations.of(UserServiceAutoConfiguration.class));
```

Tip

If multiple auto-configurations have to be defined, there is no need to order their declarations as they are invoked in the exact same order as when running the application.

Each test can use the runner to represent a particular use case. For instance, the sample below invokes a user configuration (UserConfiguration) and checks that the auto-configuration backs off properly. Invoking run provides a callback context that can be used with Assert4J.

It is also possible to easily customize the Environment, as shown in the following example:

```
@Test
public void serviceNameCanBeConfigured() {
    this.contextRunner.withPropertyValues("user.name=test123").run((context) -> {
        assertThat(context).hasSingleBean(UserService.class);
        assertThat(context.getBean(UserService.class).getName()).isEqualTo("test123");
    });
}
```

Simulating a Web Context

If you need to test an auto-configuration that only operates in a Servlet or Reactive web application context, use the WebApplicationContextRunner of ReactiveWebApplicationContextRunner respectively.

Overriding the Classpath

It is also possible to test what happens when a particular class and/or package is not present at runtime. Spring Boot ships with a FilteredClassLoader that can easily be used by the runner. In the following example, we assert that if UserService is not present, the auto-configuration is properly disabled:

```
@Test
public void serviceIsIgnoredIfLibraryIsNotPresent() {
   this.contextRunner.withClassLoader(new FilteredClassLoader(UserService.class))
    .run((context) -> assertThat(context).doesNotHaveBean("userService"));
}
```

48.5 Creating Your Own Starter

A full Spring Boot starter for a library may contain the following components:

- The autoconfigure module that contains the auto-configuration code.
- The starter module that provides a dependency to the autoconfigure module as well as the library and any additional dependencies that are typically useful. In a nutshell, adding the starter should provide everything needed to start using that library.

Tip

You may combine the auto-configuration code and the dependency management in a single module if you do not need to separate those two concerns.

Naming

You should make sure to provide a proper namespace for your starter. Do not start your module names with <code>spring-boot</code>, even if you use a different Maven <code>groupId</code>. We may offer official support for the thing you auto-configure in the future.

As a rule of thumb, you should name a combined module after the starter. For example, assume that you are creating a starter for "acme" and that you name the auto-configure module acme-spring-boot-autoconfigure and the starter acme-spring-boot-starter. If you only have one module that combines the two, name it acme-spring-boot-starter.

Also, if your starter provides configuration keys, use a unique namespace for them. In particular, do not include your keys in the namespaces that Spring Boot uses (such as server, management, spring, and so on). If you use the same namespace, we may modify these namespaces in the future in ways that break your modules.

Make sure to <u>trigger meta-data generation</u> so that IDE assistance is available for your keys as well. You may want to review the generated meta-data (META-INF/spring-configuration-metadata.json) to make sure your keys are properly documented.

autoconfigure Module

The autoconfigure module contains everything that is necessary to get started with the library. It may also contain configuration key definitions (such as @ConfigurationProperties) and any callback interface that can be used to further customize how the components are initialized.

Tip

You should mark the dependencies to the library as optional so that you can include the autoconfigure module in your projects more easily. If you do it that way, the library is not provided and, by default, Spring Boot backs off.

Starter Module

The starter is really an empty jar. Its only purpose is to provide the necessary dependencies to work with the library. You can think of it as an opinionated view of what is required to get started.

Do not make assumptions about the project in which your starter is added. If the library you are auto-configuring typically requires other starters, mention them as well. Providing a proper set of *default* dependencies may be hard if the number of optional dependencies is high, as you should avoid including dependencies that are unnecessary for a typical usage of the library. In other words, you should not include optional dependencies.

Note

Either way, your starter must reference the core Spring Boot starter (spring-boot-starter) directly or indirectly (i.e. no need to add it if your starter relies on another starter). If a project

is created with only your custom starter, Spring Boot's core features will be honoured by the presence of the core starter.

49. What to Read Next

If you want to learn more about any of the classes discussed in this section, you can check out the <u>Spring</u> <u>Boot API documentation</u> or you can browse the <u>source code directly</u>. If you have specific questions, take a look at the <u>how-to</u> section.

If you are comfortable with Spring Boot's core features, you can continue on and read about <u>production-ready features</u>.

Part V. Spring Boot Actuator: Production-ready features

Spring Boot includes a number of additional features to help you monitor and manage your application when you push it to production. You can choose to manage and monitor your application by using HTTP endpoints or with JMX. Auditing, health, and metrics gathering can also be automatically applied to your application.

50. Enabling Production-ready Features

The <u>spring-boot-actuator</u> module provides all of Spring Boot's production-ready features. The simplest way to enable the features is to add a dependency to the <u>spring-boot-starter-actuator</u> 'Starter'.

Definition of Actuator

An actuator is a manufacturing term that refers to a mechanical device for moving or controlling something. Actuators can generate a large amount of motion from a small change.

To add the actuator to a Maven based project, add the following 'Starter' dependency:

```
<dependencies>
  <dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-actuator</artifactId>
    </dependency>
  </dependencies>
```

For Gradle, use the following declaration:

```
dependencies {
  compile("org.springframework.boot:spring-boot-starter-actuator")
}
```

51. Endpoints

Actuator endpoints let you monitor and interact with your application. Spring Boot includes a number of built-in endpoints and lets you add your own. For example, the health endpoint provides basic application health information.

The way that endpoints are exposed depends on the type of technology that you choose. Most applications choose HTTP monitoring, where the ID of the endpoint along with a prefix of /actuator is mapped to a URL. For example, by default, the health endpoint is mapped to /actuator/health.

The following technology-agnostic endpoints are available:

ID	Description
auditevents	Exposes audit events information for the current application.
beans	Displays a complete list of all the Spring beans in your application.
conditions	Shows the conditions that were evaluated on configuration and auto- configuration classes and the reasons why they did or did not match.
configprops	Displays a collated list of all @ConfigurationProperties.
env	Exposes properties from Spring's ConfigurableEnvironment.
flyway	Shows any Flyway database migrations that have been applied.
health	Shows application health information.
info	Displays arbitrary application info.
loggers	Shows and modifies the configuration of loggers in the application.
liquibase	Shows any Liquibase database migrations that have been applied.
metrics	Shows 'metrics' information for the current application.
mappings	Displays a collated list of all @RequestMapping paths.
scheduledtasks	Displays the scheduled tasks in your application.
sessions	Allows retrieval and deletion of user sessions from a Spring Session- backed session store. Not available when using Spring Session's support for reactive web applications.
shutdown	Lets the application be gracefully shutdown (not enabled by default).
threaddump	Performs a thread dump.
trace	Displays trace information (by default, the last 100 HTTP requests).

If your application is a web application (Spring MVC, Spring WebFlux, or Jersey), you can use the following additional endpoints:

ID	Description
heapdump	Returns a GZip compressed hprof heap dump file.

ID	Description
logfile	Returns the contents of the logfile (if logging.file or logging.path properties have been set). Supports the use of the HTTP Range header to retrieve part of the log file's content.
prometheus	Exposes metrics in a format that can be scraped by a Prometheus server.

To learn more about the Actuator's endpoints and their request and response formats, please refer to the separate API documentation (<u>HTML</u> or <u>PDF</u>).

51.1 Exposing Endpoints

Since Endpoints may contain sensitive information, careful consideration should be given about when to expose them. By default, Spring Boot exposes all enabled endpoints over JMX but only the health and info endpoints over HTTP.

To change the endpoints that are exposed, you can use the expose and exclude property for the technology. For example, to only expose the health over JMX you would set the following property:

application.properties.

```
management.endpoints.jmx.expose=health
```

The * character can be used to indicate all endpoints. For example, to expose everything over HTTP except the env endpoint, you would use the following properties:

application.properties.

```
management.endpoints.web.exclude=env
```

Note

If your application is exposed publicly, we strongly recommend that you also <u>secure your</u> endpoints.

Tip

If you want to implement your own strategy for when endpoints are exposed, you can register an <code>EndpointFilter</code> bean.

51.2 Securing HTTP Endpoints

You should take care to secure HTTP endpoints in the same way that you would any other sensitive URL. If Spring Security is present, endpoints are secured by default using Spring Security's content-negotiation strategy. If you wish to configure custom security for HTTP endpoints, for example, only allow users with a certain role to access them, Spring Boot provides some convenient RequestMatcher objects that can be used in combination with Spring Security.

A typical Spring Security configuration might look something like the following example:

@Configuration

```
public class ActuatorSecurity extends WebSecurityConfigurerAdapter {

@Override
protected void configure(HttpSecurity http) throws Exception {
  http.requestMatcher(EndpointRequest.toAnyEndpoint()).authorizeRequests()
    .anyRequest().hasRole("ENDPOINT_ADMIN")
    .and()
    .httpBasic();
}
```

The preceding example uses <code>EndpointRequest.toAnyEndpoint()</code> to match a request to any endpoint and then ensures that all have the <code>ENDPOINT_ADMIN</code> role. Several other matcher methods are also available on <code>EndpointRequest</code>. See the API documentation (HTML or PDF) for details.

If you deploy applications behind a firewall, you may prefer that all your actuator endpoints can be accessed without requiring authentication. You can do so by changing the management.endpoints.web.expose property, as follows:

application.properties.

```
management.endpoints.web.expose=*
```

Additionally, if Spring Security is present, you would need to add custom security configuration that allows unauthenticated access to the endpoints. For example,

```
@Configuration
public class ActuatorSecurity extends WebSecurityConfigurerAdapter {
    @Override
    protected void configure(HttpSecurity http) throws Exception {
        http.requestMatcher(EndpointRequest.toAnyEndpoint()).authorizeRequests()
        .anyRequest().permitAll()
    }
}
```

51.3 Customizing Endpoints

Endpoints can be customized by using Spring properties. You can change whether an endpoint is enabled and the amount of time for which it caches responses.

For example, the following application.properties file changes the time-to-live of the beans endpoint to 10 seconds and also enables shutdown:

```
management.endpoint.beans.cache.time-to-live=10s
management.endpoint.shutdown.enabled=true
```

Note

The prefix management.endpoint.<name> is used to uniquely identify the endpoint that is being configured.

By default, all endpoints except for shutdown are enabled. If you prefer to specifically "opt-in" endpoint enablement, you can use the management.endpoints.enabled-by-default property. For example, the following settings disable *all* endpoints except for info:

```
management.endpoints.enabled-by-default=false
management.endpoint.info.enabled=true
```

Note

Disabled endpoints are removed entirely from the ApplicationContext. If you want to change only the technologies over which an endpoint is exposed, you can use the expose and exclude properties (see Section 51.1, "Exposing Endpoints").

51.4 Hypermedia for Actuator Web Endpoints

A "discovery page" is added with links to all the endpoints. The "discovery page" is available on / actuator by default.

When a custom management context path is configured, the "discovery page" automatically moves from /actuator to the root of the management context. For example, if the management context path is / management, then the discovery page is available from /management. When the management context path is set to /, the discovery page is disabled to prevent the possibility of a clash with other mappings.

51.5 Actuator Web Endpoint Paths

By default, endpoints are exposed over HTTP under the /actuator path by using the ID of the endpoint. For example, the beans endpoint is exposed under /actuator/beans. If you want to map endpoints to a different path, you can use the management.endpoints.web.path-mapping property. Also, if you want change the base path, you can use management.endpoints.web.base-path.

The following example remaps /actuator/health to /healthcheck:

application.properties.

```
management.endpoints.web.base-path=/
management.endpoints.web.path-mapping.health=healthcheck
```

51.6 CORS Support

<u>Cross-origin resource sharing</u> (CORS) is a <u>W3C specification</u> that lets you specify in a flexible way what kind of cross-domain requests are authorized. If you use Spring MVC or Spring WebFlux, Actuator's web endpoints can be configured to support such scenarios.

CORS support is disabled by default and is only enabled once the management.endpoints.web.cors.allowed-origins property has been set. The following configuration permits GET and POST calls from the example.com domain:

```
management.endpoints.web.cors.allowed-origins=http://example.com
management.endpoints.web.cors.allowed-methods=GET,POST
```

Tip

See CorsEndpointProperties for a complete list of options.

51.7 Adding Custom Endpoints

If you add a @Bean annotated with @Endpoint, any methods annotated with @ReadOperation, @WriteOperation, or @DeleteOperation are automatically exposed over JMX and, in a web application, over HTTP as well.

You can also write technology-specific endpoints by using @JmxEndpoint or @WebEndpoint. These endpoints are filtered to their respective technologies. For example, @WebEndpoint is exposed only over HTTP and not over JMX.

Finally, you can write technology-specific extensions by using <code>@EndpointWebExtension</code> and <code>@EndpointJmxExtension</code>. These annotations let you provide technology-specific operations to augment an existing endpoint.

Tip

If you add endpoints as a library feature, consider adding a configuration class annotated with @ManagementContextConfiguration to /META-INF/spring.factories under the following key:

org.springframework.boot.actuate.autoconfigure.ManagementContextConfiguration. If you do so and if your users ask for a separate management port or address, the endpoint moves to a child context with all the other web endpoints.

51.8 Health Information

You can use health information to check the status of your running application. It is often used by monitoring software to alert someone when a production system goes down. The information exposed by the health endpoint depends on the management.endpoint.health.show-details property. By default, the property's value is false and a simple "status" message is returned. When the property's value is set to true, additional details from the individual health indicators are also displayed.

Health information is collected from all <u>HealthIndicator</u> beans defined in your ApplicationContext. Spring Boot includes a number of auto-configured HealthIndicators, and you can also write your own. By default, the final system state is derived by the HealthAggregator, which sorts the statuses from each HealthIndicator based on an ordered list of statuses. The first status in the sorted list is used as the overall health status. If no HealthIndicator returns a status that is known to the HealthAggregator, an UNKNOWN status is used.

Auto-configured HealthIndicators

The following HealthIndicators are auto-configured by Spring Boot when appropriate:

Name	Description
CassandraHealthIndicator	Checks that a Cassandra database is up.
DiskSpaceHealthIndicator	Checks for low disk space.
<u>DataSourceHealthIndicator</u>	Checks that a connection to DataSource can be obtained.
ElasticsearchHealthIndicator	Checks that an Elasticsearch cluster is up.
InfluxDbHealthIndicator	Checks that an InfluxDB server is up.
<u>JmsHealthIndicator</u>	Checks that a JMS broker is up.
MailHealthIndicator	Checks that a mail server is up.

Name	Description
MongoHealthIndicator	Checks that a Mongo database is up.
Neo4jHealthIndicator	Checks that a Neo4j server is up.
RabbitHealthIndicator	Checks that a Rabbit server is up.
RedisHealthIndicator	Checks that a Redis server is up.
SolrHealthIndicator	Checks that a Solr server is up.

Tip

You can disable them all by setting the management.health.defaults.enabled property.

Writing Custom HealthIndicators

To provide custom health information, you can register Spring beans that implement the https://example.com/healthlndicator interface. You need to provide an implementation of the health() method and return a Health response. The Health response should include a status and can optionally include additional details to be displayed. The following code shows a sample HealthIndicator implementation:

```
import org.springframework.boot.actuate.health.Health;
import org.springframework.boot.actuate.health.HealthIndicator;
import org.springframework.stereotype.Component;

@Component
public class MyHealthIndicator implements HealthIndicator {

@Override
public Health health() {
  int errorCode = check(); // perform some specific health check
  if (errorCode != 0) {
    return Health.down().withDetail("Error Code", errorCode).build();
  }
  return Health.up().build();
}
```

Note

The identifier for a given ${\tt HealthIndicator}$ is the name of the bean without the ${\tt HealthIndicator}$ suffix, if it exists. In the preceding example, the health information is available in an entry named ${\tt my}$.

In addition to Spring Boot's predefined <u>Status</u> types, it is also possible for <u>Health</u> to return a custom <u>Status</u> that represents a new system state. In such cases, a custom implementation of the <u>HealthAggregator</u> interface also needs to be provided, or the default implementation has to be configured by using the <u>management.health.status.order</u> configuration property.

For example, assume a new Status with code FATAL is being used in one of your HealthIndicator implementations. To configure the severity order, add the following property to your application properties:

```
management.health.status.order=FATAL, DOWN, OUT_OF_SERVICE, UNKNOWN, UP
```

The HTTP status code in the response reflects the overall health status (for example, UP maps to 200, while OUT_OF_SERVICE and DOWN map to 503). You might also want to register custom status mappings if you access the health endpoint over HTTP. For example, the following property maps FATAL to 503 (service unavailable):

```
management.health.status.http-mapping.FATAL=503
```

Tip

If you need more control, you can define your own HealthStatusHttpMapper bean.

The following table shows the default status mappings for the built-in statuses:

Status	Mapping
DOWN	SERVICE_UNAVAILABLE (503)
OUT_OF_SERVICE	SERVICE_UNAVAILABLE (503)
UP	No mapping by default, so http status is 200
UNKNOWN	No mapping by default, so http status is 200

Reactive Health Indicators

For reactive applications, such as those using Spring WebFlux, ReactiveHealthIndicator provides a non-blocking contract for getting application health. Similar to a traditional HealthIndicator, health information is collected from all ReactiveHealthIndicator beans defined in your ApplicationContext. Regular HealthIndicator beans that do not check against a reactive API are included and executed on the elastic scheduler.

To provide custom health information from a reactive API, you can register Spring beans that implement the <u>ReactiveHealthIndicator</u> interface. The following code shows a sample ReactiveHealthIndicator implementation:

Tip

To handle the error automatically, consider extending from AbstractReactiveHealthIndicator.

Auto-configured ReactiveHealthIndicators

The following ReactiveHealthIndicators are auto-configured by Spring Boot when appropriate:

Name	Description
RedisReactiveH	e <u>€hecks that atRe</u> dis server is up.

Tip

If necessary, reactive indicators replace the regular ones. Also, any HealthIndicator that is not handled explicitly is wrapped automatically.

51.9 Application Information

Application information exposes various information collected from all <u>InfoContributor</u> beans defined in your <u>ApplicationContext</u>. Spring Boot includes a number of auto-configured <u>InfoContributor</u> beans, and you can write your own.

Auto-configured InfoContributors

The following InfoContributor beans are auto-configured by Spring Boot, when appropriate:

Name	Description
EnvironmentInfo	Exposes any key from the Environment under the info key.
GitInfoContrib	ս Exposes git information if a git.properties file is available .
BuildInfoContr	<u>i Expos</u> es build information if a META-INF/build-info.properties file is available.

Tip

It is possible to disable them all by setting the management.info.defaults.enabled property.

Custom Application Information

You can customize the data exposed by the info endpoint by setting info.* Spring properties. All Environment properties under the info key are automatically exposed. For example, you could add the following settings to your application.properties file:

```
info.app.encoding=UTF-8
info.app.java.source=1.8
info.app.java.target=1.8
```

Tip

Rather than hardcoding those values, you could also expand info properties at build time.

Assuming you use Maven, you could rewrite the preceding example as follows:

```
info.app.encoding=@project.build.sourceEncoding@
info.app.java.source=@java.version@
info.app.java.target=@java.version@
```

Git Commit Information

Another useful feature of the info endpoint is its ability to publish information about the state of your git source code repository when the project was built. If a GitProperties bean is available, the git.branch, git.commit.id, and git.commit.time properties are exposed.

Tip

A GitProperties bean is auto-configured if a git.properties file is available at the root of the classpath. See "Generate git information" for more details.

If you want to display the full git information (that is, the full content of git.properties), use the management.info.git.mode property, as follows:

```
management.info.git.mode=full
```

Build Information

If a BuildProperties bean is available, the info endpoint can also publish information about your build. This happens if a META-INF/build-info.properties file is available in the classpath.

Tip

The Maven and Gradle plugins can both generate that file. See "Generate build information" for more details.

Writing Custom InfoContributors

To provide custom application information, you can register Spring beans that implement the InfoContributor interface.

The following example contributes an example entry with a single value:

If you reach the info endpoint, you should see a response that contains the following additional entry:

```
{
    "example": {
        "key": "value"
      }
}
```

52. Monitoring and Management over HTTP

If you are developing a web application, Spring Boot Actuator auto-configures all enabled endpoints to be exposed over HTTP. The default convention is to use the id of the endpoint with a prefix of / actuator as the URL path. For example, health is exposed as /actuator/health.

Tip

Actuator is supported natively with Spring MVC, Spring WebFlux, and Jersey.

52.1 Customizing the Management Endpoint Paths

Sometimes, it is useful to customize the prefix for the management endpoints. For example, your application might already use /actuator for another purpose. You can use the management.endpoints.web.base-path property to change the prefix for your management endpoint, as shown in the following example:

```
management.endpoints.web.base-path=/manage
```

The preceding application.properties example changes the endpoint from /actuator/{id} to /manage/{id} (for example, /manage/info).

Note

Unless the management port has been configured to expose endpoints by using a different HTTP port, management.endpoints.web.base-path is relative to server.servlet.context-path. If management.server.port is configured, management.endpoints.web.base-path is relative to management.server.servlet.context-path.

52.2 Customizing the Management Server Port

Exposing management endpoints by using the default HTTP port is a sensible choice for cloud-based deployments. If, however, your application runs inside your own data center, you may prefer to expose endpoints by using a different HTTP port.

You can set the management.server.port property to change the HTTP port, as shown in the following example:

```
management.server.port=8081
```

52.3 Configuring Management-specific SSL

When configured to use a custom port, the management server can also be configured with its own SSL by using the various management.server.ssl.* properties. For example, doing so lets a management server be available over HTTP while the main application uses HTTPS, as shown in the following property settings:

```
server.port=8443
server.ssl.enabled=true
server.ssl.key-store=classpath:store.jks
server.ssl.key-password=secret
management.server.port=8080
management.server.ssl.enabled=false
```

Alternatively, both the main server and the management server can use SSL but with different key stores, as follows:

```
server.port=8443
server.ssl.enabled=true
server.ssl.key-store=classpath:main.jks
server.ssl.key-password=secret
management.server.port=8080
management.server.ssl.enabled=true
management.server.ssl.key-store=classpath:management.jks
management.server.ssl.key-password=secret
```

52.4 Customizing the Management Server Address

You can customize the address that the management endpoints are available on by setting the management.server.address property. Doing so can be useful if you want to listen only on an internal or ops-facing network or to listen only for connections from localhost.

Note

You can listen on a different address only when the port differs from the main server port.

The following example application.properties does not allow remote management connections:

```
management.server.port=8081
management.server.address=127.0.0.1
```

52.5 Disabling HTTP Endpoints

If you do not want to expose endpoints over HTTP, you can set the management port to -1, as shown in the following example:

```
management.server.port=-1
```

53. Monitoring and Management over JMX

Java Management Extensions (JMX) provide a standard mechanism to monitor and manage applications. By default, Spring Boot exposes management endpoints as JMX MBeans under the org.springframework.boot domain.

53.1 Customizing MBean Names

The name of the MBean is usually generated from the id of the endpoint. For example, the health endpoint is exposed as org.springframework.boot:type=Endpoint,name=Health.

If your application contains more than one Spring ApplicationContext, you may find that names clash. To solve this problem, you can set the management.endpoints.jmx.unique-names property to true so that MBean names are always unique.

You can also customize the JMX domain under which endpoints are exposed. The following settings show an example of doing so in application.properties:

```
management.endpoints.jmx.domain=com.example.myapp
management.endpoints.jmx.unique-names=true
```

53.2 Disabling JMX Endpoints

If you do not want to expose endpoints over JMX, you can set the management.endpoints.jmx.enabled property to false, as shown in the following example:

```
management.endpoints.jmx.enabled=false
```

53.3 Using Jolokia for JMX over HTTP

Jolokia is a JMX-HTTP bridge that provides an alternative method of accessing JMX beans. To use Jolokia, include a dependency to org.jolokia:jolokia-core. For example, with Maven, you would add the following dependency:

```
<dependency>
<groupId>org.jolokia</groupId>
<artifactId>jolokia-core</artifactId>
</dependency>
```

Jolokia can then be accessed by using /actuator/jolokia on your management HTTP server.

Customizing Jolokia

Jolokia has a number of settings that you would traditionally configure by setting servlet parameters. With Spring Boot, you can use your application.properties file. To do so, prefix the parameter with management.jolokia.config., as shown in the following example:

```
management.jolokia.config.debug=true
```

Disabling Jolokia

If you use Jolokia but do not want Spring Boot to configure it, set the management.jolokia.enabled property to false, as follows:

management.jolokia.enabled=false

54. Loggers

Spring Boot Actuator includes the ability to view and configure the log levels of your application at runtime. You can view either the entire list or an individual logger's configuration, which is made up of both the explicitly configured logging level as well as the effective logging level given to it by the logging framework. These levels can be one of:

- TRACE
- DEBUG
- INFO
- WARN
- ERROR
- FATAL
- OFF
- null

null indicates that there is no explicit configuration.

54.1 Configure a Logger

To configure a given logger, POST a partial entity to the resource's URI, as shown in the following example:

```
{
    "configuredLevel": "DEBUG"
}
```

Tip

To "reset" the specific level of the logger (and use the default configuration instead), you can pass a value of null as the configuredLevel.

55. Metrics

Spring Boot Actuator provides dependency management and auto-configuration for <u>Micrometer</u>, an application metrics facade that supports numerous monitoring systems, including:

- Atlas
- Datadog
- Ganglia
- Graphite
- Influx
- Prometheus

Note

At the time of this writing, the number of monitoring systems supported by Micrometer is growing rapidly. See the <u>Micrometer project</u> for more information.

Micrometer provides a separate module for each supported monitoring system. Depending on one (or more) of these modules is sufficient to get started with Micrometer in your Spring Boot application. To learn more about Micrometer's capabilities, please refer to its <u>reference documentation</u>.

55.1 Spring MVC Metrics

Auto-configuration enables the instrumentation of requests handled by Spring MVC. When management.metrics.web.server.auto-time-requests is true, this instrumentation occurs for all requests. Alternatively, when set to false, you can enable instrumentation by adding @Timed to a request-handling method.

By default, metrics are generated with the name, http.server.requests. The name can be customized by setting the management.metrics.web.server.requests-metric-name property.

Spring MVC Metric Tags

By default, Spring MVC-related metrics are tagged with the following information:

- The request's method.
- The request's URI (templated if possible).
- · The simple class name of any exception that was thrown while handling the request.
- The response's status.

To customize the tags, provide a @Bean that implements WebMvcTagsProvider.

55.2 WebFlux Metrics

Auto-configuration enables the instrumentation of all requests handled by WebFlux controllers. You can also use a helper class, RouterFunctionMetrics, to instrument applications that use WebFlux's functional programming model.

By default, metrics are generated with the name http.server.requests. You can customize the name by setting the management.metrics.web.server.requests-metric-name property.

WebFlux Metrics Tags

By default, WebFlux-related metrics for the annotation-based programming model are tagged with the following information:

- The request's method.
- The request's URI (templated if possible).
- The simple class name of any exception that was thrown while handling the request.
- The response's status.

To customize the tags, provide a @Bean that implements WebFluxTagsProvider.

By default, metrics for the functional programming model are tagged with the following information:

- The request's method
- The request's URI (templated if possible).
- The response's status.

To customize the tags, use the defaultTags method on your RouterFunctionMetrics instance.

55.3 RestTemplate Metrics

The instrumentation of any RestTemplate created using the auto-configured RestTemplateBuilder is enabled. It is also possible to apply MetricsRestTemplateCustomizer manually.

By default, metrics are generated with the name, http.client.requests. The name can be customized by setting the management.metrics.web.client.requests-metric-name property.

RestTemplate Metric Tags

By default, metrics generated by an instrumented RestTemplate are tagged with the following information:

- The request's method.
- The request's URI (templated if possible).
- The response's status.
- The request URI's host.

55.4 Cache metrics

Auto-configuration will enable the instrumentation of all available Caches on startup with a metric named cache. The prefix can be customized by using the management.metrics.cache.cache.

metric-name property. Cache instrumentation is specific to each cache library, refer to the micrometer documentation for more details.

The following cache libraries are supported:

- Caffeine
- EhCache 2
- Hazelcast
- Any compliant JCache (JSR-107) implementation

Metrics will also be tagged by the name of the CacheManager computed based on the bean name.

Note

Only caches that are available on startup are bound to the registry. For caches created on-the-fly or programmatically after the startup phase, an explicit registration is required. A CacheMetricsRegistrar bean is made available to make that process easier.

55.5 DataSource Metrics

Auto-configuration enables the instrumentation of all available DataSource objects with a metric named data.source. Data source instrumentation results in gauges representing the currently active, maximum allowed, and minimum allowed connections in the pool. Each of these gauges has a name that is prefixed by data.source by default. The prefix can be customized by setting the management.metrics.jdbc.datasource-metric-name property.

Metrics are also tagged by the name of the DataSource computed based on the bean name.

55.6 Spring Integration Metrics

Auto-configuration enables binding of a number of Spring Integration-related metrics:

Table 55.1. General metrics

Metric	Description
spring.integration.channelNames	Number of Spring Integration channels
spring.integration.handlerNames	Number of Spring Integration handlers
spring.integration.sourceNames	Number of Spring Integration sources

Table 55.2. Channel metrics

Metric	Description
spring.integration.channel.receives	Number of receives
spring.integration.channel.sendErrors	Number of failed sends
spring.integration.channel.sends	Number of successful sends

Table 55.3. Handler metrics

Metric	Description
spring.integration.handler.duration.m	aMaximum handler duration in milliseconds
spring.integration.handler.duration.m	iMinimum handler duration in milliseconds
spring.integration.handler.duration.m	dean handler duration in milliseconds
spring.integration.handler.activeCoun	tNumber of active handlers

Table 55.4. Source metrics

Metric	Description
spring.integration.source.messages	Number of successful source calls

56. Auditing

Once Spring Security is in play, Spring Boot Actuator has a flexible audit framework that publishes events (by default, "authentication success", "failure" and "access denied" exceptions). This feature can be very useful for reporting and for implementing a lock-out policy based on authentication failures. To customize published security events, you can provide your own implementations of AbstractAuthenticationAuditListener and AbstractAuthorizationAuditListener.

You can also use the audit services for your own business events. To do so, either inject the existing AuditEventRepository into your own components and use that directly or publish an AuditApplicationEvent with the Spring ApplicationEventPublisher (by implementing ApplicationEventPublisherAware).

57. Tracing

Tracing is automatically enabled for all HTTP requests. You can view the trace endpoint and obtain basic information about the last 100 requests. The following listing shows sample output:

```
"timestamp": 1394343677415,
 "info": {
  "method": "GET".
  "path": "/trace",
  "headers": {
   "request": {
    "Accept": "text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8",
    "Connection": "keep-alive",
    "Accept-Encoding": "gzip, deflate",
    "User-Agent": "Mozilla/5.0 Gecko/Firefox",
    "Accept-Language": "en-US, en;q=0.5",
    "Cookie": "_ga=GA1.1.827067509.1390890128; ..."
    "Authorization": "Basic ...",
    "Host": "localhost:8080"
   "response": {
    "Strict-Transport-Security": "max-age=31536000; includeSubDomains",
    "X-Application-Context": "application:8080",
    "Content-Type": "application/json; charset=UTF-8",
    "status": "200"
 }
},{
 "timestamp": 1394343684465,
}]
```

By default, the trace includes the following information:

Name	Description
Request Headers	Headers from the request.
Response Headers	Headers from the response.
Cookies	Cookie from request headers and Set-Cookie from response headers.
Errors	The error attributes (if any).
Time Taken	The time taken to service the request in milliseconds.

57.1 Custom tracing

If you need to trace additional events, you can inject a <u>TraceRepository</u> into your Spring beans. The add method accepts a single Map structure that is converted to JSON and logged.

By default, an InMemoryTraceRepository that stores the last 100 events is used. If you need to expand the capacity, you can define your own instance of the InMemoryTraceRepository bean. You can also create your own alternative TraceRepository implementation.

58. Process Monitoring

In the spring-boot module, you can find two classes to create files that are often useful for process monitoring:

- ApplicationPidFileWriter creates a file containing the application PID (by default, in the application directory with a file name of application.pid).
- EmbeddedServerPortFileWriter creates a file (or files) containing the ports of the embedded server (by default, in the application directory with a file name of application.port).

By default, these writers are not activated, but you can enable:

- By Extending Configuration
- Section 58.2, "Programmatically"

58.1 Extending Configuration

In the META-INF/spring.factories file, you can activate the listener(s) that writes a PID file, as shown in the following example:

```
org.springframework.context.ApplicationListener=\
org.springframework.boot.system.ApplicationPidFileWriter,\
org.springframework.boot.system.EmbeddedServerPortFileWriter
```

58.2 Programmatically

You can also activate a listener by invoking the SpringApplication.addListeners(...) method and passing the appropriate Writer object. This method also lets you customize the file name and path in the Writer constructor.

59. Cloud Foundry Support

Spring Boot's actuator module includes additional support that is activated when you deploy to a compatible Cloud Foundry instance. The /cloudfoundryapplication path provides an alternative secured route to all @Endpoint beans.

The extended support lets Cloud Foundry management UIs (such as the web application that you can use to view deployed applications) be augmented with Spring Boot actuator information. For example, an application status page may include full health information instead of the typical "running" or "stopped" status.

Note

The /cloudfoundryapplication path is not directly accessible to regular users. In order to use the endpoint, a valid UAA token must be passed with the request.

59.1 Disabling Extended Cloud Foundry Actuator Support

If you want to fully disable the /cloudfoundryapplication endpoints, you can add the following setting to your application.properties file:

application.properties.

```
management.cloudfoundry.enabled=false
```

59.2 Cloud Foundry Self-signed Certificates

By default, the security verification for /cloudfoundryapplication endpoints makes SSL calls to various Cloud Foundry services. If your Cloud Foundry UAA or Cloud Controller services use self-signed certificates, you need to set the following property:

application.properties.

```
management.cloudfoundry.skip-ssl-validation=true
```

59.3 Custom Security Configuration

If you define custom security configuration and you want extended Cloud Foundry actuator support, you should ensure that /cloudfoundryapplication/** paths are open. Without a direct open route, your Cloud Foundry application manager is not able to obtain endpoint data.

For Spring Security, you typically include something like mvcMatchers("/cloudfoundryapplication/**").permitAll() in your configuration, as shown in the following example:

```
@Override
protected void configure(HttpSecurity http) throws Exception {
  http
    .authorizeRequests()
    .mvcMatchers("/cloudfoundryapplication/**")
    .permitAll()
    .mvcMatchers("/mypath")
    .hasAnyRole("SUPERUSER")
    .anyRequest()
```

```
.authenticated().and()
.httpBasic();
}
```

60. What to Read Next

If you want to explore some of the concepts discussed in this chapter, you can take a look at the actuator <u>sample applications</u>. You also might want to read about graphing tools such as <u>Graphite</u>.

Otherwise, you can continue on, to read about 'deployment options' or jump ahead for some in-depth information about Spring Boot's *build tool plugins*.

Part VI. Deploying Spring Boot Applications

Spring Boot's flexible packaging options provide a great deal of choice when it comes to deploying your application. You can deploy Spring Boot applications to a variety of cloud platforms, to container images (such as Docker), or to virtual/real machines.

(such as Docker), or to virtual/real machines.		
This section covers some of the more common deployment scenarios.		

61. Deploying to the Cloud

Spring Boot's executable jars are ready-made for most popular cloud PaaS (Platform-as-a-Service) providers. These providers tend to require that you "bring your own container". They manage application processes (not Java applications specifically), so they need an intermediary layer that adapts *your* application to the *cloud's* notion of a running process.

Two popular cloud providers, Heroku and Cloud Foundry, employ a "buildpack" approach. The buildpack wraps your deployed code in whatever is needed to *start* your application. It might be a JDK and a call to <code>java</code>, an embedded web server, or a full-fledged application server. A buildpack is pluggable, but ideally you should be able to get by with as few customizations to it as possible. This reduces the footprint of functionality that is not under your control. It minimizes divergence between development and production environments.

Ideally, your application, like a Spring Boot executable jar, has everything that it needs to run packaged within it.

In this section, we look at what it takes to get the <u>simple application that we developed</u> in the "Getting Started" section up and running in the Cloud.

61.1 Cloud Foundry

Cloud Foundry provides default buildpacks that come into play if no other buildpack is specified. The Cloud Foundry <u>Java buildpack</u> has excellent support for Spring applications, including Spring Boot. You can deploy stand-alone executable jar applications as well as traditional .war packaged applications.

Once you have built your application (by using, for example, mvn clean package) and have installed the cf command line tool, deploy your application by using the cf push command, substituting the path to your compiled . jar. Be sure to have logged in with your cf command line client before pushing an application. The following line shows using the cf push command to deploy an application:

```
$ cf push acloudyspringtime -p target/demo-0.0.1-SNAPSHOT.jar
```

Note

In the preceding example, we substitute acloudyspringtime for whatever value you give cf as the name of your application.

See the <u>cf_push_documentation</u> for more options. If there is a Cloud Foundry <u>manifest.yml</u> file present in the same directory, it is considered.

At this point, cf starts uploading your application, producing output similar to the following example:

```
-----> Downloading Container Certificate Trust Store 1.0.0_RELEASE from https://java-buildpack.cloudfoundry.org/container-certificate-trust-store/container-certificate-trust-store-1.0.0_RELEASE.jar (found in cache)
    Adding certificates to .java-buildpack/container_certificate_trust_store/truststore.jks (0.6s)
-----> Downloading Spring Auto Reconfiguration 1.10.0_RELEASE from https://java-buildpack.cloudfoundry.org/auto-reconfiguration/auto-reconfiguration-1.10.0_RELEASE.jar (found in cache)
Checking status of app 'acloudyspringtime'...
0 of 1 instances running (1 starting)
...
0 of 1 instances running (1 starting)
...
1 of 1 instances running (1 starting)
App started
```

Congratulations! The application is now live!

Once your application is live, you can verify the status of the deployed application by using the cf apps command, as shown in the following example:

Once Cloud Foundry acknowledges that your application has been deployed, you should be able to find the application at the URI given. In the preceding example, you could find it at http://acloudyspringtime.cfapps.io/.

Binding to Services

By default, metadata about the running application as well as service connection information is exposed to the application as environment variables (for example: \$VCAP_SERVICES). This architecture decision is due to Cloud Foundry's polyglot (any language and platform can be supported as a buildpack) nature. Process-scoped environment variables are language agnostic.

Environment variables do not always make for the easiest API, so Spring Boot automatically extracts them and flattens the data into properties that can be accessed through Spring's Environment abstraction, as shown in the following example:

```
@Component
class MyBean implements EnvironmentAware {
    private String instanceId;

@Override
public void setEnvironment(Environment environment) {
    this.instanceId = environment.getProperty("vcap.application.instance_id");
}

// ...
}
```

All Cloud Foundry properties are prefixed with vcap. You can use vcap properties to access application information (such as the public URL of the application) and service information (such as database credentials). See the 'CloudFoundryVcapEnvironmentPostProcessor' Javadoc for complete details.

Tip

The <u>Spring Cloud Connectors</u> project is a better fit for tasks such as configuring a DataSource. Spring Boot includes auto-configuration support and a spring-boot-starter-cloud-connectors starter.

61.2 Heroku

Heroku is another popular PaaS platform. To customize Heroku builds, you provide a Procfile, which provides the incantation required to deploy an application. Heroku assigns a port for the Java application to use and then ensures that routing to the external URI works.

You must configure your application to listen on the correct port. The following example shows the Procfile for our starter REST application:

```
web: java -Dserver.port=$PORT -jar target/demo-0.0.1-SNAPSHOT.jar
```

Spring Boot makes -D arguments available as properties accessible from a Spring Environment instance. The server.port configuration property is fed to the embedded Tomcat, Jetty, or Undertow instance, which then uses the port when it starts up. The \$PORT environment variable is assigned to us by the Heroku PaaS.

This should be everything you need. The most common deployment workflow for Heroku deployments is to git push the code to production, as shown in the following example:

```
$ git push heroku master
Initializing repository, done.
Counting objects: 95, done.
Delta compression using up to 8 threads.
Compressing objects: 100% (78/78), done.
Writing objects: 100% (95/95), 8.66 MiB | 606.00 KiB/s, done.
Total 95 (delta 31), reused 0 (delta 0)

```

master -> master

Your application should now be up and running on Heroku.

61.3 OpenShift

<u>OpenShift</u> is the Red Hat public (and enterprise) extension of the Kubernetes container orchestration platform. Similarly to Kubernetes, OpenShift has many options for installing Spring Boot based applications.

OpenShift has many resources describing how to deploy Spring Boot applications, including:

- Using the S2I builder
- · Architecture guide
- Running as a traditional web application on Wildfly
- OpenShift Commons Briefing

61.4 Amazon Web Services (AWS)

Amazon Web Services offers multiple ways to install Spring Boot-based applications, either as traditional web applications (war) or as executable jar files with an embedded web server. The options include:

- · AWS Elastic Beanstalk
- AWS Code Deploy
- AWS OPS Works
- AWS Cloud Formation
- AWS Container Registry

Each has different features and pricing models. In this document, we describe only the simplest option: AWS Elastic Beanstalk.

AWS Elastic Beanstalk

As described in the official <u>Elastic Beanstalk Java guide</u>, there are two main options to deploy a Java application. You can either use the "Tomcat Platform" or the "Java SE platform".

Using the Tomcat Platform

This option applies to Spring Boot projects that produce a war file. No special configuration is required. You need only follow the official guide.

Using the Java SE Platform

This option applies to Spring Boot projects that produce a jar file and run an embedded web container. Elastic Beanstalk environments run an nginx instance on port 80 to proxy the actual application, running on port 5000. To configure it, add the following line to your application.properties file:

server.port=5000

Upload binaries instead of sources

By default, Elastic Beanstalk uploads sources and compiles them in AWS. However, it is best to upload the binaries instead. To do so, add lines similar to the following to your .elasticbeanstalk/config.yml file:

```
deploy:
    artifact: target/demo-0.0.1-SNAPSHOT.jar
```

Reduce costs by setting the environment type

By default an Elastic Beanstalk environment is load balanced. The load balancer has a significant cost. To avoid that cost, set the environment type to "Single instance", as described in the Amazon documentation. You can also create single instance environments by using the CLI and the following command:

```
eb create -s
```

Summary

This is one of the easiest ways to get to AWS, but there are more things to cover, such as how to integrate Elastic Beanstalk into any CI / CD tool, use the Elastic Beanstalk Maven plugin instead of the CLI, and others. There is a example/ [blog post] covering these topics more in detail.

61.5 Boxfuse and Amazon Web Services

<u>Boxfuse</u> works by turning your Spring Boot executable jar or war into a minimal VM image that can be deployed unchanged either on VirtualBox or on AWS. Boxfuse comes with deep integration for Spring Boot and uses the information from your Spring Boot configuration file to automatically configure ports and health check URLs. Boxfuse leverages this information both for the images it produces as well as for all the resources it provisions (instances, security groups, elastic load balancers, and so on).

Once you have created a <u>Boxfuse account</u>, connected it to your AWS account, installed the latest version of the Boxfuse Client, and ensured that the application has been built by Maven or Gradle (by using, for example, mvn clean package), you can deploy your Spring Boot application to AWS with a command similar to the following:

```
$ boxfuse run myapp-1.0.jar -env=prod
```

See the <u>boxfuse run documentation</u> for more options. If there is a <u>boxfuse.com/docs/commandline/</u>
#configuration [boxfuse.conf] file present in the current directory, it is considered.

Tip

By default, Boxfuse activates a Spring profile named boxfuse on startup. If your executable jar or war contains an boxfuse.properties] file, Boxfuse bases its configuration on the properties it contains.

At this point, boxfuse creates an image for your application, uploads it, and configures and starts the necessary resources on AWS, resulting in output similar to the following example:

```
Fusing Image for myapp-1.0.jar ...
Image fused in 00:06.838s (53937 K) -> axelfontaine/myapp:1.0
Creating axelfontaine/myapp ...
Pushing axelfontaine/myapp:1.0 ...
Verifying axelfontaine/myapp:1.0 ...
Creating Elastic IP ...
Mapping myapp-axelfontaine.boxfuse.io to 52.28.233.167 ...
Waiting for AWS to create an AMI for axelfontaine/myapp:1.0 in eu-central-1 (this may take up to 50
seconds) ...
AMI created in 00:23.557s -> ami-d23f38cf
Creating security group boxfuse-sg_axelfontaine/myapp:1.0 ...
Launching t2.micro instance of axelfontaine/myapp:1.0 (ami-d23f38cf) in eu-central-1 ...
Instance launched in 00:30.306s -> i-92ef9f53
Waiting for AWS to boot Instance i-92ef9f53 and Payload to start at http://52.28.235.61/ ...
Payload started in 00:29.266s -> http://52.28.235.61/
Remapping Elastic IP 52.28.233.167 to i-92ef9f53 ...
Waiting 15s for AWS to complete Elastic IP Zero Downtime transition ...
Deployment completed successfully. axelfontaine/myapp:1.0 is up and running at http://myapp-
axelfontaine.boxfuse.io/
```

Your application should now be up and running on AWS.

See the blog post on <u>deploying Spring Boot apps on EC2</u> as well as the <u>documentation for the Boxfuse Spring Boot integration</u> to get started with a Maven build to run the app.

61.6 Google Cloud

Google Cloud has several options that can be used to launch Spring Boot applications. The easiest to get started with is probably App Engine, but you could also find ways to run Spring Boot in a container with Container Engine or on a virtual machine with Compute Engine.

To run in App Engine, you can create a project in the UI first, which sets up a unique identifier for you and also sets up HTTP routes. Add a Java app to the project and leave it empty and then use the <u>Google Cloud SDK</u> to push your Spring Boot app into that slot from the command line or CI build.

App Engine needs you to create an app.yaml file to describe the resources your app requires. Normally, you put this file in src/main/appengine, and it should resemble the following file:

```
service: default

runtime: java
env: flex

runtime_config:
    jdk: openjdk8

handlers:
- url: /.*
    script: this field is required, but ignored

manual_scaling:
    instances: 1

health_check:
    enable_health_check: False

env_variables:
    ENCRYPT_KEY: your_encryption_key_here
```

You can deploy the app (for example, with a Maven plugin) by adding the project ID to the build configuration, as shown in the following example:

```
<plugin>
```

```
<groupId>com.google.cloud.tools</groupId>
<artifactId>appengine-maven-plugin</artifactId>
<version>1.3.0</version>
<configuration>
  cproject>myproject</project>
</plugin>
```

Then deploy with mvn appengine: deploy (if you need to authenticate first, the build fails).

Note

Google App Engine Classic is tied to the Servlet 2.5 API, so you cannot deploy a Spring Application there without some modifications. See the <u>Servlet 2.5 section</u> of this guide.

62. Installing Spring Boot Applications

In additional to running Spring Boot applications by using <code>java -jar</code>, it is also possible to make fully executable applications for Unix systems. A fully executable jar can be executed like any other executable binary or it can be registered with init.dorsystemd. This makes it very easy to install and manage Spring Boot applications in common production environments.

Caution

Fully executable jars work by embedding an extra script at the front of the file. Currently, some tools do not accept this format, so you may not always be able to use this technique. For example, jar -xf may silently fail to extract a jar or war that has been made fully executable. It is recommended that you make your jar or war fully executable only if you intend to execute it directly, rather than running it with java -jar or deploying it to a servlet container.

To create a 'fully executable' jar with Maven, use the following plugin configuration:

```
<plugin>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-maven-plugin</artifactId>
  <configuration>
   <executable>true</executable>
  </configuration>
  </plugin>
```

The following example shows the equivalent Gradle configuration:

```
bootJar {
  launchScript()
}
```

You can then run your application by typing . /my-application.jar (where my-application is the name of your artifact). The directory containing the jar is used as your application's working directory.

62.1 Supported Operating Systems

The default script supports most Linux distributions and is tested on CentOS and Ubuntu. Other platforms, such as OS X and FreeBSD, require the use of a custom embeddedLaunchScript.

62.2 Unix/Linux Services

Spring Boot application can be easily started as Unix/Linux services by using either init.d or systemd.

Installation as an init.d Service (System V)

If you configured Spring Boot's Maven or Gradle plugin to generate a <u>fully executable jar</u>, and you do not use a custom <code>embeddedLaunchScript</code>, your application can be used as an <code>init.d</code> service. To do so, symlink the jar to <code>init.d</code> to support the standard <code>start</code>, <code>stop</code>, <code>restart</code>, and <code>status</code> commands.

The script supports the following features:

- Starts the services as the user that owns the jar file
- Tracks the application's PID by using /var/run/<appname>/<appname>.pid

• Writes console logs to /var/log/<appname>.log

Assuming that you have a Spring Boot application installed in /var/myapp, to install a Spring Boot application as an init.d service, create a symlink, as follows:

```
$ sudo ln -s /var/myapp/myapp.jar /etc/init.d/myapp
```

Once installed, you can start and stop the service in the usual way. For example, on a Debian-based system, you could start it with the following command:

```
$ service myapp start
```

Tip

If your application fails to start, check the log file written to /var/log/<appname>.log for errors.

You can also flag the application to start automatically by using your standard operating system tools. For example, on Debian, you could use the following command:

```
$ update-rc.d myapp defaults <priority>
```

Securing an init.d Service

Note

The following is a set of guidelines on how to secure a Spring Boot application that runs as an init.d service. It is not intended to be an exhaustive list of everything that should be done to harden an application and the environment in which it runs.

When executed as root, as is the case when root is being used to start an init.d service, the default executable script runs the application as the user who owns the jar file. You should never run a Spring Boot application as root, so your application's jar file should never be owned by root. Instead, create a specific user to run your application and use chown to make it the owner of the jar file, as shown in the following example:

```
$ chown bootapp:bootapp your-app.jar
```

In this case, the default executable script runs the application as the bootapp user.

Tip

To reduce the chances of the application's user account being compromised, you should consider preventing it from using a login shell. For example, you can set the account's shell to /usr/sbin/nologin.

You should also take steps to prevent the modification of your application's jar file. Firstly, configure its permissions so that it cannot be written and can only be read or executed by its owner, as shown in the following example:

```
$ chmod 500 your-app.jar
```

Second, you should also take steps to limit the damage if your application or the account that's running it is compromised. If an attacker does gain access, they could make the jar file writable and change its

contents. One way to protect against this is to make it immutable by using chattr, as shown in the following example:

```
$ sudo chattr +i your-app.jar
```

This will prevent any user, including root, from modifying the jar.

If root is used to control the application's service and you use a .conf file to customize its startup, the .conf file is read and evaluated by the root user. It should be secured accordingly. Use chmod so that the file can only be read by the owner and use chown to make root the owner, as shown in the following example:

```
$ chmod 400 your-app.conf
$ sudo chown root:root your-app.conf
```

Installation as a systemd Service

systemd is the successor of the System V init system and is now being used by many modern Linux distributions. Although you can continue to use init.d scripts with systemd, it is also possible to launch Spring Boot applications by using systemd 'service' scripts.

Assuming that you have a Spring Boot application installed in <code>/var/myapp</code>, to install a Spring Boot application as a <code>systemd</code> service, create a script named <code>myapp.service</code> and place it in <code>/etc/systemd/system</code> directory. The following script offers an example:

```
[Unit]
Description=myapp
After=syslog.target

[Service]
User=myapp
ExecStart=/var/myapp/myapp.jar
SuccessExitStatus=143

[Install]
WantedBy=multi-user.target
```

Important

Remember to change the Description, User, and ExecStart fields for your application.

Note

The ExecStart field does not declare the script action command, which means that the run command is used by default.

Note that, unlike when running as an init.d service, the user that runs the application, the PID file, and the console log file are managed by systemd itself and therefore must be configured by using appropriate fields in the 'service' script. Consult the service unit configuration man page for more details.

To flag the application to start automatically on system boot, use the following command:

```
$ systemctl enable myapp.service
```

Refer to man systematl for more details.

Customizing the Startup Script

The default embedded startup script written by the Maven or Gradle plugin can be customized in a number of ways. For most people, using the default script along with a few customizations is usually enough. If you find you cannot customize something that you need to, use the <code>embeddedLaunchScript</code> option to write your own file entirely.

Customizing the Start Script when It Is Written

It often makes sense to customize elements of the start script as it is written into the jar file. For example, init.d scripts can provide a "description". Since you know the description up front (and it need not change), you may as well provide it when the jar is generated.

To customize written elements, use the <code>embeddedLaunchScriptProperties</code> option of the Spring Boot Maven or Gradle plugins.

The following property substitutions are supported with the default script:

Name	Description
mode	The script mode. Defaults to auto.
initInfoPr	owniedes section of "INIT INFO". Defaults to spring-boot-application for Gradle and to \${project.artifactId} for Maven.
initInfoRe	q Theresquare d-Start section of "INIT INFO". Defaults to \$remote_fs \$syslog \$network.
initInfoRe	q The Rel ន្ថែងចំទ្រed-Stop section of "INIT INFO". Defaults to \$remote_fs \$syslog \$network.
initInfoDe	fand Datantt-Start section of "INIT INFO". Defaults to 2 3 4 5.
initInfoDe	fand Dataplt-Stop section of "INIT INFO". Defaults to 0 1 6.
initInfoSh	oFheesboripDescription section of "INIT INFO". Defaults to Spring Boot Application for Gradle and to \${project.name} for Maven.
initInfoDe	sThe pesomiption section of "INIT INFO". Defaults to Spring Boot Application for Gradle and to \${project.description} (falling back to \${project.name}) for Maven.
initInfoCh	ւk Եխ ունիացconfig section of "INIT INFO". Defaults to 2345 99 01.
confFolder	The default value for CONF_FOLDER. Defaults to the folder containing the jar.
inlinedCon	fReference to a file script that should be inlined in the default launch script. This can be used to set environmental variables such as JAVA_OPTS before any external config files are loaded.
logFolder	The default value for LOG_FOLDER. Only valid for an init.d service.
logFilenam	eThe default value for LOG_FILENAME. Only valid for an init.d service.
pidFolder	The default value for PID_FOLDER. Only valid for an init.d service.
pidFilenam	eThe default value for the name of the PID file in PID_FOLDER. Only valid for an init.d service.

Name	Description
useStartSt	ophibether the start-stop-daemon command, when it's available, should be used to control the process. Defaults to true.
stopWaitTi	mehe default value for STOP_WAIT_TIME. Only valid for an init.d service. Defaults to 60 seconds.

Customizing a Script When It Runs

For items of the script that need to be customized *after* the jar has been written, you can use environment variables or a <u>config file</u>.

The following environment properties are supported with the default script:

Variable	Description
MODE	The "mode" of operation. The default depends on the way the jar was built but is usually auto (meaning it tries to guess if it is an init script by checking if it is a symlink in a directory called init.d). You can explicitly set it to service so that the stop start status restart commands work or to run if you want to run the script in the foreground.
USE_START_	SWIVE there it's available, should be used to control the process. Defaults to true.
PID_FOLDER	The root name of the pid folder (/var/run by default).
LOG_FOLDER	The name of the folder in which to put log files (/var/log by default).
CONF_FOLDE	RThe name of the folder from which to read .conf files (same folder as jar-file by default).
LOG_FILENA	MEhe name of the log file in the LOG_FOLDER (<appname>.log by default).</appname>
APP_NAME	The name of the app. If the jar is run from a symlink, the script guesses the app name. If it is not a symlink or you want to explicitly set the app name, this can be useful.
RUN_ARGS	The arguments to pass to the program (the Spring Boot app).
JAVA_HOME	The location of the java executable is discovered by using the PATH by default, but you can set it explicitly if there is an executable file at \$JAVA_HOME/bin/java.
JAVA_OPTS	Options that are passed to the JVM when it is launched.
JARFILE	The explicit location of the jar file, in case the script is being used to launch a jar that it is not actually embedded.
DEBUG	If not empty, sets the $-\mathbf{x}$ flag on the shell process, making it easy to see the logic in the script.
STOP_WAIT_	Time time in seconds to wait when stopping the application before forcing a shutdown (60 by default).

Note

The PID_FOLDER, LOG_FOLDER, and LOG_FILENAME variables are only valid for an init.d service. For systemd, the equivalent customizations are made by using the 'service' script. See the <u>service unit configuration man page</u> for more details.

With the exception of JARFILE and APP_NAME, the settings listed in the preceding section can be configured by using a .conf file. The file is expected to be next to the jar file and have the same name but suffixed with .conf rather than .jar. For example, a jar named /var/myapp/myapp.jar uses the configuration file named /var/myapp/myapp.conf, as shown in the following example:

myapp.conf.

JAVA_OPTS=-Xmx1024M
LOG_FOLDER=/custom/log/folder

Tip

If you do not like having the config file next to the jar file, you can set a CONF_FOLDER environment variable to customize the location of the config file.

To learn about securing this file appropriately, see the guidelines for securing an init.d service.

62.3 Microsoft Windows Services

A Spring Boot application can be started as a Windows service by using winsw.

A (<u>separately maintained sample</u>) describes step-by-step how you can create a Windows service for your Spring Boot application.

63. What to Read Next

Check out the <u>Cloud Foundry</u>, <u>Heroku</u>, <u>OpenShift</u>, and <u>Boxfuse</u> web sites for more information about the kinds of features that a PaaS can offer. These are just four of the most popular Java PaaS providers. Since Spring Boot is so amenable to cloud-based deployment, you can freely consider other providers as well.

The next section goes on to cover the <u>Spring Boot CLI</u>, or you can jump ahead to read about <u>build</u> <u>tool plugins</u>.

Part VII. Spring Boot CLI

The Spring Boot CLI is a command line tool that you can use if you want to quickly develop a Spring application. It lets you run Groovy scripts, which means that you have a familiar Java-like syntax without so much boilerplate code. You can also bootstrap a new project or write your own command for it.

64. Installing the CLI

The Spring Boot CLI (Command-Line Interface) can be installed manually by using SDKMAN! (the SDK Manager) or by using Homebrew or MacPorts if you are an OSX user. See <u>Section 10.2</u>, "<u>Installing the Spring Boot CLI"</u> in the "Getting started" section for comprehensive installation instructions.

65. Using the CLI

Once you have installed the CLI, you can run it by typing spring and pressing Enter at the command line. If you run spring without any arguments, a simple help screen is displayed, as follows:

You can type spring help to get more details about any of the supported commands, as shown in the following example:

```
$ spring help run
spring run - Run a spring groovy script
usage: spring run [options] <files> [--] [args]
Option
                          Description
--autoconfigure [Boolean] Add autoconfigure compiler
                            transformations (default: true)
transformations (default: t --classpath, -cp Additional classpath entries
                        Open the file with the default system
                           editor
--no-guess-dependencies Do not attempt to guess dependencies
--no-guess-imports Do not attempt to guess imports
-q, --quiet
-v, --verbose
                          Quiet logging
                          Verbose logging of dependency
                            resolution
--watch
                          Watch the specified file for changes
```

The version command provides a quick way to check which version of Spring Boot you are using, as follows:

```
$ spring version
Spring CLI v2.0.0.BUILD-SNAPSHOT
```

65.1 Running Applications with the CLI

You can compile and run Groovy source code by using the run command. The Spring Boot CLI is completely self-contained, so you do not need any external Groovy installation.

The following example shows a "hello world" web application written in Groovy:

hello.groovy.

```
@RestController
class WebApplication {

@RequestMapping("/")
String home() {
  "Hello World!"
}
```

To compile and run the application, type the following command:

```
$ spring run hello.groovy
```

To pass command-line arguments to the application, use -- to separate the commands from the "spring" command arguments, as shown in the following example:

```
$ spring run hello.groovy -- --server.port=9000
```

To set JVM command line arguments, you can use the <code>JAVA_OPTS</code> environment variable, as shown in the following example:

```
$ JAVA_OPTS=-Xmx1024m spring run hello.groovy
```

Note

When setting JAVA_OPTS on Microsoft Windows, make sure to quote the entire instruction, such as set "JAVA_OPTS=-Xms256m -Xmx2048m". Doing so ensures the values are properly passed to the process.

Deduced "grab" Dependencies

Standard Groovy includes a @Grab annotation, which lets you declare dependencies on third-party libraries. This useful technique lets Groovy download jars in the same way as Maven or Gradle would but without requiring you to use a build tool.

Spring Boot extends this technique further and tries to deduce which libraries to "grab" based on your code. For example, since the <code>WebApplication</code> code shown previously uses <code>@RestController</code> annotations, Spring Boot grabs "Tomcat" and "Spring MVC".

The following items are used as "grab hints":

Items	Grabs
JdbcTemplate, NamedParameterJdbcTemplate, DataSource	JDBC Application.
@EnableJms	JMS Application.
@EnableCaching	Caching abstraction.
@Test	JUnit.
@EnableRabbit	RabbitMQ.
@EnableReactor	Project Reactor.
extends Specification	Spock test.
@EnableBatchProcessing	Spring Batch.
@MessageEndpoint @EnableIntegration	Spring Integration.
@Controller @RestController @EnableWebMvc	Spring MVC + Embedded Tomcat.

Items	Grabs
@EnableWebSecurity	Spring Security.
@EnableTransactionManagement	Spring Transaction Management.

Tip

See subclasses of <u>CompilerAutoConfiguration</u> in the Spring Boot CLI source code to understand exactly how customizations are applied.

Deduced "grab" Coordinates

Spring Boot extends Groovy's standard @Grab support by letting you specify a dependency without a group or version (for example, @Grab('freemarker')). Doing so consults Spring Boot's default dependency metadata to deduce the artifact's group and version.

Note

The default metadata is tied to the version of the CLI that you use. it changes only when you move to a new version of the CLI, putting you in control of when the versions of your dependencies may change. A table showing the dependencies and their versions that are included in the default metadata can be found in the <u>appendix</u>.

Default Import Statements

To help reduce the size of your Groovy code, several import statements are automatically included. Notice how the preceding example refers to @Component, @RestController, and @RequestMapping without needing to use fully-qualified names or import statements.

Tip

Many Spring annotations work without using import statements. Try running your application to see what fails before adding imports.

Automatic Main Method

Unlike the equivalent Java application, you do not need to include a public static void main(String[] args) method with your Groovy scripts. A SpringApplication is automatically created, with your compiled code acting as the source.

Custom Dependency Management

By default, the CLI uses the dependency management declared in spring-boot-dependencies when resolving @Grab dependencies. Additional dependency management, which overrides the default dependency management, can be configured by using the @DependencyManagementBom annotation. The annotation's value should specify the coordinates (groupId:artifactId:version) of one or more Mayen BOMs.

For example, consider the following declaration:

@DependencyManagementBom("com.example.custom-bom:1.0.0")

The preceding declaration picks up custom-bom-1.0.0.pom in a Maven repository under com/example/custom-versions/1.0.0/.

When you specify multiple BOMs, they are applied in the order in which you declare them, as shown in the following example:

```
@DependencyManagementBom(["com.example.custom-bom:1.0.0",
    "com.example.another-bom:1.0.0"])
```

The preceding example indicates that the dependency management in another-bom overrides the dependency management in custom-bom.

You can use @DependencyManagementBom anywhere that you can use @Grab. However, to ensure consistent ordering of the dependency management, you can use @DependencyManagementBom at most once in your application. A useful source of dependency management (which is a superset of Spring Boot's dependency management) is the Spring IO Platform, which you might include with the following line:

```
@DependencyManagementBom('io.spring.platform:platform-bom:1.1.2.RELEASE')
```

65.2 Applications with Multiple Source Files

You can use "shell globbing" with all commands that accept file input. Doing so lets you use multiple files from a single directory, as shown in the following example:

```
$ spring run *.groovy
```

65.3 Packaging Your Application

You can use the jar command to package your application into a self-contained executable jar file, as shown in the following example:

```
$ spring jar my-app.jar *.groovy
```

The resulting jar contains the classes produced by compiling the application and all of the application's dependencies so that it can then be run by using <code>java -jar</code>. The jar file also contains entries from the application's classpath. You can add and remove explicit paths to the jar by using <code>--include</code> and <code>--exclude</code>. Both are comma-separated, and both accept prefixes, in the form of "+" and "-", to signify that they should be removed from the defaults. The default includes are as follows:

```
public/**, resources/**, static/**, templates/**, META-INF/**, *
```

The default excludes are as follows:

```
.*, repository/**, build/**, target/**, **/*.jar, **/*.groovy
```

Type spring help jar on the command line for more information.

65.4 Initialize a New Project

The init command lets you create a new project by using <u>start.spring.io</u> without leaving the shell, as shown in the following example:

```
$ spring init --dependencies=web,data-jpa my-project
Using service at https://start.spring.io
Project extracted to '/Users/developer/example/my-project'
```

The preceding example creates a my-project directory with a Maven-based project that uses spring-boot-starter-web and spring-boot-starter-data-jpa. You can list the capabilities of the service by using the --list flag, as shown in the following example:

The init command supports many options. See the help output for more details. For instance, the following command creates a Gradle project that uses Java 8 and war packaging:

```
$ spring init --build=gradle --java-version=1.8 --dependencies=websocket --packaging=war sample-app.zip
Using service at https://start.spring.io
Content saved to 'sample-app.zip'
```

65.5 Using the Embedded Shell

Spring Boot includes command-line completion scripts for the BASH and zsh shells. If you do not use either of these shells (perhaps you are a Windows user), you can use the shell command to launch an integrated shell, as shown in the following example:

```
$ spring shell
Spring Boot (v2.0.0.BUILD-SNAPSHOT)
Hit TAB to complete. Type \'help' and hit RETURN for help, and \'exit' to quit.
```

From inside the embedded shell, you can run other commands directly:

```
$ version
Spring CLI v2.0.0.BUILD-SNAPSHOT
```

The embedded shell supports ANSI color output as well as tab completion. If you need to run a native command, you can use the ! prefix. To exit the embedded shell, press ctrl-c.

65.6 Adding Extensions to the CLI

You can add extensions to the CLI by using the install command. The command takes one or more sets of artifact coordinates in the format group:artifact:version, as shown in the following example:

```
$ spring install com.example:spring-boot-cli-extension:1.0.0.RELEASE
```

In addition to installing the artifacts identified by the coordinates you supply, all of the artifacts' dependencies are also installed.

To uninstall a dependency, use the uninstall command. As with the install command, it takes one or more sets of artifact coordinates in the format of group:artifact:version, as shown in the following example:

```
$ spring uninstall com.example:spring-boot-cli-extension:1.0.0.RELEASE
```

It uninstalls the artifacts identified by the coordinates you supply and their dependencies.

To uninstall all additional dependencies, you can use the --all option, as shown in the following example:

```
$ spring uninstall --all
```

66. Developing Applications with the Groovy Beans DSL

Spring Framework 4.0 has native support for a beans {} "DSL" (borrowed from <u>Grails</u>), and you can embed bean definitions in your Groovy application scripts by using the same format. This is sometimes a good way to include external features like middleware declarations, as shown in the following example:

```
@Configuration
class Application implements CommandLineRunner {
    @Autowired
    SharedService service

    @Override
    void run(String... args) {
        println service.message
    }
}

import my.company.SharedService

beans {
    service(SharedService) {
        message = "Hello World"
    }
}
```

You can mix class declarations with beans {} in the same file as long as they stay at the top level, or, if you prefer, you can put the beans DSL in a separate file.

67. Configuring the CLI with settings.xml

The Spring Boot CLI uses Aether, Maven's dependency resolution engine, to resolve dependencies. The CLI makes use of the Maven configuration found in $\sim/.m2/settings.xml$ to configure Aether. The following configuration settings are honored by the CLI:

- Offline
- Mirrors
- Servers
- Proxies
- Profiles
 - Activation
 - Repositories
- · Active profiles

See Maven's settings documentation for further information.

68. What to Read Next

There are some <u>sample groovy scripts</u> available from the GitHub repository that you can use to try out the Spring Boot CLI. There is also extensive Javadoc throughout the <u>source code</u>.

If you find that you reach the limit of the CLI tool, you probably want to look at converting your application to a full Gradle or Maven built "Groovy project". The next section covers Spring Boot's "Build tool plugins", which you can use with Gradle or Maven.

Part VIII. Build tool plugins

Spring Boot provides build tool plugins for Maven and Gradle. The plugins offer a variety of features, including the packaging of executable jars. This section provides more details on both plugins as well as some help should you need to extend an unsupported build system. If you are just getting started, you might want to read "Chapter 13, Build Systems" from the "Part III, "Using Spring Boot" section first.

69. Spring Boot Maven Plugin

The <u>Spring Boot Maven Plugin</u> provides Spring Boot support in Maven, letting you package executable jar or war archives and run an application "in-place". To use it, you must use Maven 3.2 (or later).

Note

See the Spring Boot Maven Plugin Site for complete plugin documentation.

69.1 Including the Plugin

To use the Spring Boot Maven Plugin, include the appropriate XML in the plugins section of your pom.xml, as shown in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
<modelVersion>4.0.0</modelVersion>
<build>
 <plugins>
  <plugin>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-maven-plugin</artifactId>
  <version>2.0.0.BUILD-SNAPSHOT
   <execution>
    <goals>
     <goal>repackage</goal>
   </execution>
  </executions>
  </plugin>
 </plugins>
</build>
</project>
```

The preceding configuration repackages a jar or war that is built during the package phase of the Maven lifecycle. The following example shows both the repackaged jar as well as the original jar in the target directory:

```
$ mvn package
$ ls target/*.jar
target/myproject-1.0.0.jar target/myproject-1.0.0.jar.original
```

If you do not include the <execution/> configuration, as shown in the prior example, you can run the plugin on its own (but only if the package goal is used as well), as shown in the following example:

```
$ mvn package spring-boot:repackage
$ ls target/*.jar
target/myproject-1.0.0.jar target/myproject-1.0.0.jar.original
```

If you use a milestone or snapshot release, you also need to add the appropriate pluginRepository elements, as shown in the following listing:

```
<pluginRepositories>
<pluginRepository>
  <id>spring-snapshots</id>
  <url>http://repo.spring.io/snapshot</url>
  </pluginRepository>
  <pluginRepository></pluginRepository>
```

```
<id>spring-milestones</id>
<url>http://repo.spring.io/milestone</url>
</pluginRepository>
</pluginRepositories>
```

69.2 Packaging Executable Jar and War Files

Once spring-boot-maven-plugin has been included in your pom.xml, it automatically tries to rewrite archives to make them executable by using the spring-boot:repackage goal. You should configure your project to build a jar or war (as appropriate) by using the usual packaging element, as shown in the following example:

Your existing archive is enhanced by Spring Boot during the package phase. The main class that you want to launch can be specified either by using a configuration option or by adding a Main-Class attribute to the manifest in the usual way. If you do not specify a main class, the plugin searches for a class with a public static void main(String[] args) method.

To build and run a project artifact, you can type the following:

```
$ mvn package
$ java -jar target/mymodule-0.0.1-SNAPSHOT.jar
```

To build a war file that is both executable and deployable into an external container, you need to mark the embedded container dependencies as "provided", as shown in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
cproject xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
    <!-- ... -->
    <dependaging>war</packaging>
    <!-- ... -->
    <dependencies>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-web</artifactId>
        </dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-tomcat</artifactId>
        <scope>provided</scope>
        </dependency>
        </dependency>
        </dependency>
        </dependencies>
        </dependencies>
        </project>
```

Tip

See the "Section 88.1, "Create a Deployable War File"" section for more details on how to create a deployable war file.

Advanced configuration options and examples are available in the plugin info page.

70. Spring Boot Gradle Plugin

The Spring Boot Gradle Plugin provides Spring Boot support in Gradle, letting you package executable jar or war archives, run Spring Boot applications, and use the dependency management provided by spring-boot-dependencies. It requires Gradle 4.0 or later. Please refer to the plugin's documentation to learn more:

- Reference (HTML and PDF)
- API

71. Spring Boot AntLib Module

The Spring Boot AntLib module provides basic Spring Boot support for Apache Ant. You can use the module to create executable jars. To use the module, you need to declare an additional spring-boot namespace in your build.xml, as shown in the following example:

You need to remember to start Ant using the -lib option, as shown in the following example:

```
$ ant -lib <folder containing spring-boot-antlib-2.0.0.BUILD-SNAPSHOT.jar>
```

Tip

The "Using Spring Boot" section includes a more complete example of <u>using Apache Ant with spring-boot-antlib</u>.

71.1 Spring Boot Ant Tasks

Once the spring-boot-antlib namespace has been declared, the following additional tasks are available:

- the section called "spring-boot:exejar"
- Section 71.2, "spring-boot:findmainclass"

spring-boot:exejar

You can use the <code>exejar</code> task to create a Spring Boot executable jar. The following attributes are supported by the task:

Attribute	Description	Required
destfile	The destination jar file to create	Yes
classes	The root directory of Java class files	Yes
start-class	The main application class to run	No (the default is the first class found that declares a main method)

The following nested elements can be used with the task:

Element	Description
resources	One or more <u>Resource Collections</u> describing a set of <u>Resources</u> that should be added to the content of the created jar file.
lib	One or more Resource Collections that should be added to the set of jar libraries that make up the runtime dependency classpath of the application.

Examples

This section shows two examples of Ant tasks.

Specify start-class.

Detect start-class.

```
<exejar destfile="target/my-application.jar" classes="target/classes">
  b>
    <fileset dir="lib" />
    </lib>
  </exejar>
```

71.2 spring-boot:findmainclass

The findmainclass task is used internally by exejar to locate a class declaring a main. If necessary, you can also use this task directly in your build. The following attributes are supported:

Attribute	Description	Required
classesroot	The root directory of Java class files	Yes (unless mainclass is specified)
mainclass	Can be used to short-circuit the main class search	No
property	The Ant property that should be set with the result	No (result will be logged if unspecified)

Examples

This section contains three examples of using findmainclass.

Find and log.

```
<findmainclass classesroot="target/classes" />
```

Find and set.

```
<findmainclass classesroot="target/classes" property="main-class" />
```

Override and set.

```
<findmainclass mainclass="com.example.MainClass" property="main-class" />
```

72. Supporting Other Build Systems

If you want to use a build tool other than Maven, Gradle, or Ant, you likely need to develop your own plugin. Executable jars need to follow a specific format and certain entries need to be written in an uncompressed form (see the "executable jar format" section in the appendix for details).

The Spring Boot Maven and Gradle plugins both make use of spring-boot-loader-tools to actually generate jars. If you need to, you may use this library directly.

72.1 Repackaging Archives

To repackage an existing archive so that it becomes a self-contained executable archive, use org.springframework.boot.loader.tools.Repackager. The Repackager class takes a single constructor argument that refers to an existing jar or war archive. Use one of the two available repackage() methods to either replace the original file or write to a new destination. Various settings can also be configured on the repackager before it is run.

72.2 Nested Libraries

When repackaging an archive, you can include references to dependency files by using the org.springframework.boot.loader.tools.Libraries interface. We do not provide any concrete implementations of Libraries here as they are usually build-system-specific.

If your archive already includes libraries, you can use Libraries.NONE.

72.3 Finding a Main Class

If you do not use Repackager.setMainClass() to specify a main class, the repackager uses ASM to read class files and tries to find a suitable class with a public static void main(String[] args) method. An exception is thrown if more than one candidate is found.

72.4 Example Repackage Implementation

The following example shows a typical repackage implementation:

```
Repackager repackager = new Repackager(sourceJarFile);
repackager.setBackupSource(false);
repackager.repackage(new Libraries() {
    @Override
    public void doWithLibraries(LibraryCallback callback) throws IOException {
        // Build system specific implementation, callback for each dependency
        // callback.library(new Library(nestedFile, LibraryScope.COMPILE));
    }
});
```

73. What to Read Next

If you are interested in how the build tool plugins work, you can look at the spring-boot-tools module on GitHub. More technical details of the executable jar format are covered in the appendix.

If you have specific build-related questions, you can check out the "how-to" guides.

Part IX. 'How-to' guides

This section provides answers to some common 'how do I do that...' questions that often arise when using Spring Boot. Its coverage is not exhaustive, but it does cover quite a lot.

If you have a specific problem that we do not cover here, you might want to check out <u>stackoverflow.com</u> to see if someone has already provided an answer. This is also a great place to ask new questions (please use the <u>spring-boot</u> tag).

We are also more than happy to extend this section. If you want to add a 'how-to', send us a <u>pull request</u>.

74. Spring Boot Application

This section includes topics relating directly to Spring Boot applications.

74.1 Create Your Own FailureAnalyzer

<u>FailureAnalyzer</u> is a great way to intercept an exception on startup and turn it into a human-readable message, wrapped in a <u>FailureAnalysis</u>. Spring Boot provides such an analyzer for application-context-related exceptions, JSR-303 validations, and more. You can also create your own.

AbstractFailureAnalyzer is a convenient extension of FailureAnalyzer that checks the presence of a specified exception type in the exception to handle. You can extend from that so that your implementation gets a chance to handle the exception only when it is actually present. If, for whatever reason, you cannot handle the exception, return null to give another implementation a chance to handle the exception.

FailureAnalyzer implementations must be registered in META-INF/spring.factories. The following example registers ProjectConstraintViolationFailureAnalyzer:

```
org.springframework.boot.diagnostics.FailureAnalyzer=\
com.example.ProjectConstraintViolationFailureAnalyzer
```

Note

If you need access to the BeanFactory or the Environment, your FailureAnalyzer can simply implement BeanFactoryAware or EnvironmentAware respectively.

74.2 Troubleshoot Auto-configuration

The Spring Boot auto-configuration tries its best to "do the right thing", but sometimes things fail, and it can be hard to tell why.

There is a really useful <code>ConditionEvaluationReport</code> available in any Spring Boot <code>ApplicationContext</code>. You can see it if you enable <code>DEBUG</code> logging output. If you use the <code>springboot-actuator</code> (see the Actuator chapter), there is also a <code>conditions</code> endpoint that renders the report in JSON. Use that endpoint to debug the application and see what features have been added (and which have not been added) by Spring Boot at runtime.

Many more questions can be answered by looking at the source code and the Javadoc. When reading the code, remember the following rules of thumb:

- Look for classes called *AutoConfiguration and read their sources. Pay special attention to the @Conditional* annotations to find out what features they enable and when. Add --debug to the command line or a System property -Ddebug to get a log on the console of all the auto-configuration decisions that were made in your app. In a running Actuator app, look at the conditions endpoint (/actuator/conditions or the JMX equivalent) for the same information.
- Look for classes that are @ConfigurationProperties (such as <u>ServerProperties</u>) and read from there the available external configuration options. The @ConfigurationProperties annotation has a name attribute that acts as a prefix to external properties. Thus, ServerProperties has prefix="server" and its configuration properties are server.port, server.address, and others. In a running Actuator app, look at the configprops endpoint.

- Look for uses of the bind method on the Binder to pull configuration values explicitly out of the Environment in a relaxed manner. It is often used with a prefix.
- Look for @Value annotations that bind directly to the Environment.
- Look for @ConditionalOnExpression annotations that switch features on and off in response to SpEL expressions, normally evaluated with placeholders resolved from the Environment.

74.3 Customize the Environment or ApplicationContext Before It Starts

A SpringApplication has ApplicationListeners and ApplicationContextInitializers that are used to apply customizations to the context or environment. Spring Boot loads a number of such customizations for use internally from META-INF/spring.factories. There is more than one way to register additional customizations:

- Programmatically, per application, by calling the addListeners and addInitializers methods on SpringApplication before you run it.
- Declaratively, per application, by setting the context.initializer.classes or context.listener.classes properties.
- Declaratively, for all applications, by adding a META-INF/spring.factories and packaging a jar file that the applications all use as a library.

The SpringApplication sends some special ApplicationEvents to the listeners (some even before the context is created) and then registers the listeners for events published by the ApplicationContext as well. See "Section 23.5, "Application Events and Listeners" in the 'Spring Boot features' section for a complete list.

It is also possible to customize the Environment before the application context is refreshed by using EnvironmentPostProcessor. Each implementation should be registered in META-INF/spring.factories, as shown in the following example:

```
org.springframework.boot.env.EnvironmentPostProcessor=com.example.YourEnvironmentPostProcessor
```

The implementation can load arbitrary files and add them to the Environment. For instance, the following example loads a YAML configuration file from the classpath:

```
public class EnvironmentPostProcessorExample implements EnvironmentPostProcessor {
    private final YamlPropertySourceLoader loader = new YamlPropertySourceLoader();

    @Override
    public void postProcessEnvironment(ConfigurableEnvironment environment,
        SpringApplication application) {
        Resource path = new ClassPathResource("com/example/myapp/config.yml");
        PropertySource<?> propertySource = loadYaml(path);
        environment.getPropertySources().addLast(propertySource);
    }
    private PropertySource<?> loadYaml(Resource path) {
        if (!path.exists()) {
            throw new IllegalArgumentException("Resource " + path + " does not exist");
        }
        try {
            return this.loader.load("custom-resource", path, null);
        }
}
```

```
catch (IOException ex) {
  throw new IllegalStateException(
   "Failed to load yaml configuration from " + path, ex);
}
}
```

Tip

The Environment has already been prepared with all the usual property sources that Spring Boot loads by default. It is therefore possible to get the location of the file from the environment. The preceding example adds the <code>custom-resource</code> property source at the end of the list so that a key defined in any of the usual other locations takes precedence. A custom implementation may define another order.

Caution

While using @PropertySource on your @SpringBootApplication may seem to be a convenient and easy way to load a custom resource in the Environment, we do not recommend it, because Spring Boot prepares the Environment before the ApplicationContext is refreshed. Any key defined with @PropertySource is loaded too late to have any effect on autoconfiguration.

74.4 Build an ApplicationContext Hierarchy (Adding a Parent or Root Context)

You can use the ApplicationBuilder class to create parent/child ApplicationContext hierarchies. See "Section 23.4, "Fluent Builder API" in the 'Spring Boot features' section for more information.

74.5 Create a Non-web Application

Not all Spring applications have to be web applications (or web services). If you want to execute some code in a main method but also bootstrap a Spring application to set up the infrastructure to use, you can use the SpringApplication features of Spring Boot. A SpringApplication changes its ApplicationContext class, depending on whether it thinks it needs a web application or not. The first thing you can do to help it is to leave the servlet API dependencies off the classpath. If you cannot do that (for example, you run two applications from the same code base) then you can explicitly call setWebEnvironment(false) on your SpringApplication instance or set the applicationContextClass property (through the Java API or with external properties). Application code that you want to run as your business logic can be implemented as a CommandLineRunner and dropped into the context as a @Bean definition.

75. Properties and Configuration

This section includes topics about setting and reading properties and configuration settings and their interaction with Spring Boot applications.

75.1 Automatically Expand Properties at Build Time

Rather than hardcoding some properties that are also specified in your project's build configuration, you can automatically expand them by instead using the existing build configuration. This is possible in both Maven and Gradle.

Automatic Property Expansion Using Maven

You can automatically expand properties from the Maven project by using resource filtering. If you use the <code>spring-boot-starter-parent</code>, you can then refer to your Maven 'project properties' with @..@ placeholders, as shown in the following example:

```
app.encoding=@project.build.sourceEncoding@
app.java.version@
```

Note

Only production configuration is filtered that way (in other words, no filtering is applied on src/test/resources).

Tip

If you enable the addResources flag, the spring-boot:run goal can add src/main/resources directly to the classpath (for hot reloading purposes). Doing so circumvents the resource filtering and this feature. Instead, you can use the exec:java goal or customize the plugin's configuration. See the plugin usage page for more details.

If you do not use the starter parent, you need to include the following element inside the <build/> element of your pom.xml:

```
<resources>
<resource>
  <directory>src/main/resources</directory>
  <filtering>true</filtering>
  </resource>
</resources>
```

You also need to include the following element inside <plugins/>:

```
<plugin>
  <groupId>org.apache.maven.plugins</groupId>
  <artifactId>maven-resources-plugin</artifactId>
  <version>2.7</version>
  <configuration>
    <delimiters>
        <delimiters>
        <delimiters>
        </delimiters>
        </delimiters>
        <useDefaultDelimiters>false</useDefaultDelimiters>
        </configuration>
        </plugin>
```

Note

The useDefaultDelimiters property is important if you use standard Spring placeholders (such as \${placeholder}) in your configuration. If that property is not set to false, these may be expanded by the build.

Automatic Property Expansion Using Gradle

You can automatically expand properties from the Gradle project by configuring the Java plugin's processResources task to do so, as shown in the following example:

```
processResources {
  expand(project.properties)
}
```

You can then refer to your Gradle project's properties by using placeholders, as shown in the following example:

```
app.name=${name}
app.description=${description}
```

Note

Gradle's expand method uses Groovy's SimpleTemplateEngine, which transforms $\{...\}$ tokens. The $\{...\}$ style conflicts with Spring's own property placeholder mechanism. To use Spring property placeholders together with automatic expansion, escape the Spring property placeholders as follows: $\{...\}$.

75.2 Externalize the Configuration of SpringApplication

A SpringApplication has bean properties (mainly setters), so you can use its Java API as you create the application to modify its behavior. Alternatively, you can externalize the configuration by setting properties in spring.main.*. For example, in application.properties, you might have the following settings:

```
spring.main.web-environment=false
spring.main.banner-mode=off
```

Then the Spring Boot banner is not printed on startup, and the application is not a web application.

Note

The preceding example also demonstrates how flexible binding allows the use of underscores (_) as well as dashes (-) in property names.

Properties defined in external configuration override the values specified with the Java API, with the notable exception of the sources used to create the ApplicationContext. Consider the following application:

```
new SpringApplicationBuilder()
.bannerMode(Banner.Mode.OFF)
.sources(demo.MyApp.class)
.run(args);
```

Now consider the following configuration:

```
spring.main.sources=com.acme.Config,com.acme.ExtraConfig
spring.main.banner-mode=console
```

The actual application *now* shows the banner (as overridden by configuration) and uses three sources for the ApplicationContext (in the following order): demo.MyApp, com.acme.Config, and com.acme.ExtraConfig.

75.3 Change the Location of External Properties of an Application

By default, properties from different sources are added to the Spring Environment in a defined order (see "Chapter 24, Externalized Configuration" in the 'Spring Boot features' section for the exact order).

A nice way to augment and modify this ordering is to add @PropertySource annotations to your application sources. Classes passed to the SpringApplication static convenience methods and those added using setSources() are inspected to see if they have @PropertySources. If they do, those properties are added to the Environment early enough to be used in all phases of the ApplicationContext lifecycle. Properties added in this way have lower priority than any added by using the default locations (such as application.properties), system properties, environment variables, or the command line.

You can also provide the following System properties (or environment variables) to change the behavior:

- spring.config.name (SPRING_CONFIG_NAME): Defaults to application as the root of the file name.
- spring.config.location (SPRING_CONFIG_LOCATION): The file to load (such as a classpath resource or a URL). A separate Environment property source is set up for this document and it can be overridden by system properties, environment variables, or the command line.

No matter what you set in the environment, Spring Boot always loads application.properties as described above. By default, if YAML is used, then files with the '.yml' extension are also added to the list.

Spring Boot logs the configuration files that are loaded at the DEBUG level and the candidates it has not found at TRACE level.

See <u>ConfigFileApplicationListener</u> for more detail.

75.4 Use 'Short' Command Line Arguments

Some people like to use (for example) --port=9000 instead of --server.port=9000 to set configuration properties on the command line. You can enable this behavior by using placeholders in application.properties, as shown in the following example:

```
server.port=${port:8080}
```

Tip

If you inherit from the <code>spring-boot-starter-parent</code> POM, the default filter token of the <code>maven-resources-plugins</code> has been changed from \${*} to @ (that is, @maven.token@ instead of \${maven.token}) to prevent conflicts with Spring-style placeholders. If you have enabled Maven filtering for the <code>application.properties</code> directly, you may want to also change the default filter token to use <code>other delimiters</code>.

Note

In this specific case, the port binding works in a PaaS environment such as Heroku or Cloud Foundry. In those two platforms, the PORT environment variable is set automatically and Spring can bind to capitalized synonyms for Environment properties.

75.5 Use YAML for External Properties

YAML is a superset of JSON and, as such, is a convenient syntax for storing external properties in a hierarchical format, as shown in the following example:

```
spring:
application:
name: cruncher
datasource:
    driverClassName: com.mysql.jdbc.Driver
    url: jdbc:mysql://localhost/test
server:
port: 9000
```

Create a file called application.yml and put it in the root of your classpath. Then add snakeyaml to your dependencies (Maven coordinates org.yaml:snakeyaml, already included if you use the spring-boot-starter). A YAML file is parsed to a Java Map<String,Object> (like a JSON object), and Spring Boot flattens the map so that it is one level deep and has period-separated keys, as many people are used to with Properties files in Java.

The preceding example YAML corresponds to the following application.properties file:

```
spring.application.name=cruncher
spring.datasource.driverClassName=com.mysql.jdbc.Driver
spring.datasource.url=jdbc:mysql://localhost/test
server.port=9000
```

See "Section 24.6, "Using YAML Instead of Properties" in the 'Spring Boot features' section for more information about YAML.

75.6 Set the Active Spring Profiles

The Spring Environment has an API for this, but you would normally set a System property (spring.profiles.active) or an OS environment variable (SPRING_PROFILES_ACTIVE). Also, you can launch your application with a -D argument (remember to put it before the main class or jar archive), as follows:

```
$ java -jar -Dspring.profiles.active=production demo-0.0.1-SNAPSHOT.jar
```

In Spring Boot, you can also set the active profile in application.properties, as shown in the following example:

```
spring.profiles.active=production
```

A value set this way is replaced by the System property or environment variable setting but not by the SpringApplicationBuilder.profiles() method. Thus, the latter Java API can be used to augment the profiles without changing the defaults.

See "Chapter 25, Profiles" in the "Spring Boot features" section for more information.

75.7 Change Configuration Depending on the Environment

A YAML file is actually a sequence of documents separated by --- lines, and each document is parsed separately to a flattened map.

If a YAML document contains a spring.profiles key, then the profiles value (a comma-separated list of profiles) is fed into the Spring Environment.acceptsProfiles() method. If any of those profiles is active, that document is included in the final merge (otherwise, it is not), as shown in the following example:

```
server:
  port: 9000
---
spring:
  profiles: development
server:
  port: 9001
---
spring:
  profiles: production
server:
  port: 0
```

In the preceding example, the default port is 9000. However, if the Spring profile called 'development' is active, then the port is 9001. If 'production' is active, then the port is 0.

Note

The YAML documents are merged in the order in which they are encountered. Later values override earlier values.

To do the same thing with properties files, you can use application-\${profile}.properties to specify profile-specific values.

75.8 Discover Built-in Options for External Properties

Spring Boot binds external properties from application.properties (or .yml files and other places) into an application at runtime. There is not (and technically cannot be) an exhaustive list of all supported properties in a single location, because contributions can come from additional jar files on your classpath.

A running application with the Actuator features has a configprops endpoint that shows all the bound and bindable properties available through @ConfigurationProperties.

The appendix includes an <u>application.properties</u> example with a list of the most common properties supported by Spring Boot. The definitive list comes from searching the source code for <code>@ConfigurationProperties</code> and <code>@Value</code> annotations as well as the occasional use of <code>Binder</code>. For more about the exact ordering of loading properties, see "<u>Chapter 24</u>, <u>Externalized Configuration</u>".

76. Embedded Web Servers

Each Spring Boot web application includes an embedded web server. This feature leads to a number of how-to questions, including how to change the embedded server and how to configure the embedded server. This section answers those questions.

76.1 Use Another Web Server

Many Spring Boot starters include default embedded containers. spring-boot-starter-web includes Tomcat by including spring-boot-starter-tomcat, but you can use spring-boot-starter-jetty or spring-boot-starter-undertow instead. spring-boot-starter-webflux includes Reactor Netty by including spring-boot-starter-reactor-netty, but you can use spring-boot-starter-tomcat, spring-boot-starter-jetty, or spring-boot-starter-undertow instead.

Note

Many starters support only Spring MVC, so they transitively bring spring-boot-starter-web into your application classpath.

If you need to use a different HTTP server, you need to exclude the default dependencies and include the one you need. Spring Boot provides separate starters for HTTP servers to help make this process as easy as possible.

The following Maven example shows how to exclude Tomcat and include Jetty for Spring MVC:

```
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-web</artifactId>
  <exclusions>
  <!-- Exclude the Tomcat dependency -->
   <exclusion>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-tomcat</artifactId>
    </exclusion>
  </exclusions>
  </dependency>
  <!-- Use Jetty instead -->
  <dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-jetty</artifactId>
  </dependency>
  </dependency>
  </dependency>
  <artifactId>spring-boot-starter-jetty</artifactId>
  </dependency>
```

The following Gradle example shows how to exclude Netty and include Undertow for Spring WebFlux:

```
configurations {
   // exclude Reactor Netty
   compile.exclude module: 'spring-boot-starter-reactor-netty'
}
dependencies {
   compile 'org.springframework.boot:spring-boot-starter-webflux'
   // Use Undertow instead
   compile 'org.springframework.boot:spring-boot-starter-undertow'
   // ...
}
```

Note

spring-boot-starter-reactor-netty is required to use the WebClient class, so you may need to keep a dependency on Netty even when you need to include a different HTTP server.

76.2 Configure Jetty

Generally, you can follow the advice from "Section 75.8, "Discover Built-in Options for External Properties" about @ConfigurationProperties (ServerProperties is the main one here). However, you should also look at WebServerFactoryCustomizer. The Jetty APIs are quite rich, so, once you have access to the JettyServletWebServerFactory, you can modify it in a number of ways. Alternatively, if you need more control and customization, you can add your own JettyServletWebServerFactory.

76.3 Add a Servlet, Filter, or Listener to an Application

There are two ways to add Servlet, Filter, ServletContextListener, and the other listeners supported by the Servlet spec to your application:

- the section called "Add a Servlet, Filter, or Listener by Using a Spring Bean"
- the section called "Add Servlets, Filters, and Listeners by Using Classpath Scanning"

Add a Servlet, Filter, or Listener by Using a Spring Bean

To add a Servlet, Filter, or Servlet *Listener by using a Spring bean, you must provide a @Bean definition for it. Doing so can be very useful when you want to inject configuration or dependencies. However, you must be very careful that they do not cause eager initialization of too many other beans, because they have to be installed in the container very early in the application lifecycle. (For example, it is not a good idea to have them depend on your DataSource or JPA configuration.) You can work around such restrictions by initializing the beans lazily when first used instead of on initialization.

In the case of Filters and Servlets, you can also add mappings and init parameters by adding a FilterRegistrationBean or a ServletRegistrationBean instead of or in addition to the underlying component.

Note

If no dispatcherType is specified on a filter registration, REQUEST is used. This aligns with the Servlet Specification's default dispatcher type.

Disable Registration of a Servlet or Filter

As <u>described earlier</u>, any Servlet or Filter beans are registered with the servlet container automatically. To disable registration of a particular Filter or Servlet bean, create a registration bean for it and mark it as disabled, as shown in the following example:

```
@Bean
public FilterRegistrationBean registration(MyFilter filter) {
  FilterRegistrationBean registration = new FilterRegistrationBean(filter);
  registration.setEnabled(false);
  return registration;
}
```

Add Servlets, Filters, and Listeners by Using Classpath Scanning

<code>@WebServlet</code>, <code>@WebFilter</code>, and <code>@WebListener</code> annotated classes can be automatically registered with an embedded servlet container by annotating a <code>@Configuration</code> class with <code>@ServletComponentScan</code> and specifying the package(s) containing the components that you want to register. By default, <code>@ServletComponentScan</code> scans from the package of the annotated class.

76.4 Change the HTTP Port

In a standalone application, the main HTTP port defaults to 8080 but can be set with server.port (for example, in application.properties or as a System property). Thanks to relaxed binding of Environment values, you can also use SERVER_PORT (for example, as an OS environment variable).

To switch off the HTTP endpoints completely but still create a WebApplicationContext, use server.port=-1. (Doing so is sometimes useful for testing.)

For more details, see "the section called "Customizing Embedded Servlet Containers"" in the 'Spring Boot features' section, or the <u>ServerProperties</u> source code.

76.5 Use a Random Unassigned HTTP Port

To scan for a free port (using OS natives to prevent clashes) use server.port=0.

76.6 Discover the HTTP Port at Runtime

You can access the port the server is running on from log output or from the ServletWebServerApplicationContext through its WebServer. The best way to get that and be sure that it has been initialized is to add a @Bean of type ApplicationListener<ServletWebServerInitializedEvent> and pull the container out of the event when it is published.

Tests that use @SpringBootTest(webEnvironment=WebEnvironment.RANDOM_PORT) can also inject the actual port into a field by using the @LocalServerPort annotation, as shown in the following example:

```
@RunWith(SpringJUnit4ClassRunner.class)
@SpringBootTest(webEnvironment=WebEnvironment.RANDOM_PORT)
public class MyWebIntegrationTests {

@Autowired
ServletWebServerApplicationContext server;

@LocalServerPort
int port;

// ...
}
```

Note

@LocalServerPort is a meta-annotation for @Value(" $$\{local.server.port\}$ "). Do not try to inject the port in a regular application. As we just saw, the value is set only after the container has been initialized. Contrary to a test, application code callbacks are processed early (before the value is actually available).

76.7 Configure SSL

SSL can be configured declaratively by setting the various server.ssl.* properties, typically in application.properties or application.yml. The following example shows setting SSL properties in application.properties:

```
server.port=8443
server.ssl.key-store=classpath:keystore.jks
server.ssl.key-store-password=secret
server.ssl.key-password=another-secret
```

See Ss1 for details of all of the supported properties.

Using configuration such as the preceding example means the application no longer supports a plain HTTP connector at port 8080. Spring Boot does not support the configuration of both an HTTP connector and an HTTPS connector through application.properties. If you want to have both, you need to configure one of them programmatically. We recommend using application.properties to configure HTTPS, as the HTTP connector is the easier of the two to configure programmatically. See the spring-boot-sample-tomcat-multi-connectors sample project for an example.

76.8 Configure HTTP/2

You can enable HTTP/2 support in your Spring Boot application with the server.http2.enabled configuration property. This support depends on the chosen web server and the application environment, since that protocol is not supported out-of-the-box by JDK8.

Note

Spring Boot does not support h2c, the cleartext version of the HTTP/2 protocol. So you must configure SSL first.

Currently, only Undertow and Tomcat are supported with this configuration key.

HTTP/2 with Undertow

As of Undertow 1.4.0+, HTTP/2 is supported without any additional requirement on JDK8.

HTTP/2 with Tomcat

Spring Boot ships by default with Tomcat 8.5.x. With that version, HTTP/2 is only supported if the libtenative library and its dependencies are installed on the host operating system.

The library folder must be made available, if not already, to the JVM library path. You can do so with a JVM argument such as -Djava.library.path=/usr/local/opt/tomcat-native/lib. More on this in the official Tomcat documentation.

Starting Tomcat 8.5.x without that native support logs the following error:

```
ERROR 8787 --- [ main] o.a.coyote.http11.Http11NioProtocol : The upgrade handler [org.apache.coyote.http2.Http2Protocol] for [h2] only supports upgrade via ALPN but has been configured for the ["https-jsse-nio-8443"] connector that does not support ALPN.
```

This error is not fatal, and the application still starts with HTTP/1.1 SSL support.

Running your application with Tomcat 9.0.x and JDK9 does not require any native library to be installed. To use Tomcat 9, you can override the tomcat.version build property with the version of your choice.

76.9 Configure Access Logging

Access logs can be configured for Tomcat, Undertow, and Jetty through their respective namespaces.

For instance, the following settings log access on Tomcat with a <u>custom pattern</u>.

```
server.tomcat.basedir=my-tomcat
server.tomcat.accesslog.enabled=true
server.tomcat.accesslog.pattern=%t %a "%r" %s (%D ms)
```

Note

The default location for logs is a logs directory relative to the Tomcat base directory. By default, the logs directory is a temporary directory, so you may want to fix Tomcat's base directory or use an absolute path for the logs. In the preceding example, the logs are available in my-tomcat/logs relative to the working directory of the application.

Access logging for Undertow can be configured in a similar fashion, as shown in the following example:

```
server.undertow.accesslog.enabled=true
server.undertow.accesslog.pattern=%t %a "%r" %s (%D ms)
```

Logs are stored in a logs directory relative to the working directory of the application. You can customize this location by setting the server.undertow.accesslog.directory property.

Finally, access logging for Jetty can also be configured as follows:

```
server.jetty.accesslog.enabled=true
server.jetty.accesslog.filename=/var/log/jetty-access.log
```

By default, logs are redirected to System.err. For more details, see the Jetty documentation.

76.10 Running Behind a Front-end Proxy Server

Your application might need to send 302 redirects or render content with absolute links back to itself. When running behind a proxy, the caller wants a link to the proxy and not to the physical address of the machine hosting your app. Typically, such situations are handled through a contract with the proxy, which adds headers to tell the back end how to construct links to itself.

If the proxy adds conventional X-Forwarded-For and X-Forwarded-Proto headers (most proxy servers do so), the absolute links should be rendered correctly, provided server.use-forward-headers is set to true in your application.properties.

Note

If your application runs in Cloud Foundry or Heroku, the server.use-forward-headers property defaults to true. In all other instances, it defaults to false.

Customize Tomcat's Proxy Configuration

If you use Tomcat, you can additionally configure the names of the headers used to carry "forwarded" information, as shown in the following example:

```
server.tomcat.remote-ip-header=x-your-remote-ip-header
server.tomcat.protocol-header=x-your-protocol-header
```

Tomcat is also configured with a default regular expression that matches internal proxies that are to be trusted. By default, IP addresses in 10/8, 192.168/16, 169.254/16 and 127/8 are trusted. You can customize the valve's configuration by adding an entry to application.properties, as shown in the following example:

```
server.tomcat.internal-proxies=192 \verb|\|.168|\|.\| d\{1,3\} \verb|\|.\| d\{1,3\} \verb|\|.
```

Note

The double backslashes are required only when you use a properties file for configuration. If you use YAML, single backslashes are sufficient, and a value equivalent to that shown in the preceding example would be $192 \setminus .168 \setminus .d\{1,3\} \setminus .d\{1,3\}$.

Note

You can trust all proxies by setting the internal-proxies to empty (but do not do so in production).

You can take complete control of the configuration of Tomcat's RemotelpValve by switching the automatic one off (to do so, set server.use-forward-headers=false) and adding a new valve instance in a TomcatServletWebServerFactory bean.

76.11 Configure Tomcat

Generally, you can follow the advice from "Section 75.8, "Discover Built-in Options for External Properties" about @ConfigurationProperties (ServerProperties is the main one here). However, you should also look at WebServerFactoryCustomizer and various Tomcat-specific *Customizers that you can add. The Tomcat APIs are quite rich. Consequently, once you have access to the TomcatServletWebServerFactory, you can modify it in a number of ways. Alternatively, if you need more control and customization, you can add your own TomcatServletWebServerFactory.

76.12 Enable Multiple Connectors with Tomcat

You can add an org.apache.catalina.connector.Connector to the TomcatServletWebServerFactory, which can allow multiple connectors, including HTTP and HTTPS connectors, as shown in the following example:

```
public ServletWebServerFactory servletContainer() {
   TomcatServletWebServerFactory tomcat = new TomcatServletWebServerFactory();
   tomcat.addAdditionalTomcatConnectors(createSslConnector());
   return tomcat;
}

private Connector createSslConnector() {
   Connector connector = new Connector("org.apache.coyote.http11.Http11NioProtocol");
   Http11NioProtocol protocol = (Http11NioProtocol) connector.getProtocolHandler();
   try {
    File keystore = new ClassPathResource("keystore").getFile();
    File truststore = new ClassPathResource("keystore").getFile();
    connector.setScheme("https");
    connector.setSecure(true);
    connector.setPort(8443);
    protocol.setSSLEnabled(true);
```

```
protocol.setKeystoreFile(keystore.getAbsolutePath());
protocol.setKeystorePass("changeit");
protocol.setTruststoreFile(truststore.getAbsolutePath());
protocol.setTruststorePass("changeit");
protocol.setKeyAlias("apitester");
return connector;
}
catch (IOException ex) {
  throw new IllegalStateException("can't access keystore: [" + "keystore" + "] or truststore: [" + "keystore" + "]", ex);
}
```

76.13 Use Tomcat's LegacyCookieProcessor

By default, the embedded Tomcat used by Spring Boot does not support "Version 0" of the Cookie format, so you may see the following error:

```
java.lang.IllegalArgumentException: An invalid character [32] was present in the Cookie value
```

If at all possible, you should consider updating your code to only store values compliant with later Cookie specifications. If, however, you cannot change the way that cookies are written, you can instead configure Tomcat to use a LegacyCookieProcessor. To switch to the LegacyCookieProcessor, use an WebServerFactoryCustomizer bean that adds a TomcatContextCustomizer, as shown in the following example:

```
@Bean
public WebServerFactoryCustomizer<TomcatServletWebServerFactory> cookieProcessorCustomizer() {
  return (serverFactory) -> serverFactory.addContextCustomizers(
        (context) -> context.setCookieProcessor(new LegacyCookieProcessor()));
}
```

76.14 Configure Undertow

Generally you can follow the advice from "Section 75.8, "Discover Built-in Options for External Properties" about @ConfigurationProperties (ServerProperties ServerProperties.Undertow are the main ones here). However, you should look at WebServerFactoryCustomizer. Once you have access UndertowServletWebServerFactory, you can use an UndertowBuilderCustomizer to modify Undertow's configuration to meet your needs. Alternatively, if you need more control and customization, you can add your own UndertowServletWebServerFactory.

76.15 Enable Multiple Listeners with Undertow

Add an UndertowBuilderCustomizer to the UndertowServletWebServerFactory and add a listener to the Builder, as shown in the following example:

```
@Bean
public UndertowServletWebServerFactory servletWebServerFactory() {
  UndertowServletWebServerFactory factory = new UndertowServletWebServerFactory();
  factory.addBuilderCustomizers(new UndertowBuilderCustomizer() {
    @Override
    public void customize(Builder builder) {
        builder.addHttpListener(8080, "0.0.0.0");
    }
    });
    return factory;
}
```

76.16 Create WebSocket Endpoints Using @ServerEndpoint

If you want to use @ServerEndpoint in a Spring Boot application that used an embedded container, you must declare a single ServerEndpointExporter @Bean, as shown in the following example:

```
@Bean
public ServerEndpointExporter serverEndpointExporter() {
   return new ServerEndpointExporter();
}
```

The bean shown in the preceding example registers any @ServerEndpoint annotated beans with the underlying WebSocket container. When deployed to a standalone servlet container, this role is performed by a servlet container initializer, and the ServerEndpointExporter bean is not required.

76.17 Enable HTTP Response Compression

HTTP response compression is supported by Jetty, Tomcat, and Undertow. It can be enabled in application.properties, as follows:

```
server.compression.enabled=true
```

By default, responses must be at least 2048 bytes in length for compression to be performed. You can configure this behavior by setting the server.compression.min-response-size property.

By default, responses are compressed only if their content type is one of the following:

- text/html
- text/xml
- text/plain
- text/css

You can configure this behavior by setting the server.compression.mime-types property.

77. Spring MVC

Spring Boot has a number of starters that include Spring MVC. Note that some starters include a dependency on Spring MVC rather than include it directly. This section answers common questions about Spring MVC and Spring Boot.

77.1 Write a JSON REST Service

Any Spring @RestController in a Spring Boot application should render JSON response by default as long as Jackson2 is on the classpath, as shown in the following example:

```
@RestController
public class MyController {

    @RequestMapping("/thing")
    public MyThing thing() {
      return new MyThing();
    }
}
```

As long as MyThing can be serialized by Jackson2 (true for a normal POJO or Groovy object), then localhost:8080/thing serves a JSON representation of it by default. Note that, in a browser, you might sometimes see XML responses, because browsers tend to send accept headers that prefer XML.

77.2 Write an XML REST Service

If you have the Jackson XML extension (jackson-dataformat-xml) on the classpath, you can use it to render XML responses. The previous example that we used for JSON would work. To use the Jackson XML renderer, add the following dependency to your project:

```
<dependency>
  <groupId>com.fasterxml.jackson.dataformat</groupId>
  <artifactId>jackson-dataformat-xml</artifactId>
  </dependency>
```

You may also want to add a dependency on Woodstox. It is faster than the default StAX implementation provided by the JDK and also adds pretty-print support and improved namespace handling. The following listing shows how to include a dependency on <u>Woodstox</u>:

```
<dependency>
  <groupId>org.codehaus.woodstox</groupId>
  <artifactId>woodstox-core-asl</artifactId>
  </dependency>
```

If Jackson's XML extension is not available, JAXB (provided by default in the JDK) is used, with the additional requirement of having MyThing annotated as @XmlRootElement, as shown in the following example:

```
@XmlRootElement
public class MyThing {
  private String name;
  // .. getters and setters
}
```

To get the server to render XML instead of JSON, you might have to send an Accept: text/xml header (or use a browser).

77.3 Customize the Jackson ObjectMapper

Spring MVC (client and server side) uses HttpMessageConverters to negotiate content conversion in an HTTP exchange. If Jackson is on the classpath, you already get the default converter(s) provided by Jackson2ObjectMapperBuilder, an instance of which is auto-configured for you.

The ObjectMapper (or XmlMapper for Jackson XML converter) instance (created by default) has the following customized properties:

- MapperFeature.DEFAULT_VIEW_INCLUSION is disabled
- DeserializationFeature.FAIL_ON_UNKNOWN_PROPERTIES is disabled

Spring Boot also has some features to make it easier to customize this behavior.

You can configure the <code>ObjectMapper</code> and <code>XmlMapper</code> instances by using the environment. Jackson provides an extensive suite of simple on/off features that can be used to configure various aspects of its processing. These features are described in six enums (in Jackson) that map onto properties in the environment:

Jackson enum	Environment property	
com.fasterxml.jackson.databind.Deseri	askiziatgi.ojaRekastouradeserialization. <featu false</featu 	re_name>=tru
com.fasterxml.jackson.core.JsonGenera	t spr.Reg.tjæc kson.generator. <feature_nam false</feature_nam 	e>=true
com.fasterxml.jackson.databind.Mapper	Familing.jackson.mapper. <feature_name>= false</feature_name>	true
com.fasterxml.jackson.core.JsonParser	false	true
com.fasterxml.jackson.databind.Serial	i spattingnFjaatkusen. serialization. <feature false</feature 	_name>=true
com.fasterxml.jackson.annotation.Json	Ispring.Janksobe.default-property- inclusion=always non_null non_absent non_default non_empty	

For example, to enable pretty print, set spring.jackson.serialization.indent_output=true. Note that, thanks to the use of relaxed binding, the case of indent_output does not have to match the case of the corresponding enum constant, which is INDENT_OUTPUT.

This environment-based configuration is applied to the auto-configured <code>Jackson2ObjectMapperBuilder</code> bean and applies to any mappers created by using the builder, including the auto-configured <code>ObjectMapper</code> bean.

The context's <code>Jackson2ObjectMapperBuilder</code> can be customized by one or more <code>Jackson2ObjectMapperBuilderCustomizer</code> beans. Such customizer beans can be ordered (Boot's own customizer has an order of 0), letting additional customization be applied both before and after Boot's customization.

Any beans of type <code>com.fasterxml.jackson.databind.Module</code> are automatically registered with the auto-configured <code>Jackson2ObjectMapperBuilder</code> and are applied to any <code>ObjectMapper</code> instances that it creates. This provides a global mechanism for contributing custom modules when you add new features to your application.

If you want to replace the default ObjectMapper completely, either define a <code>@Bean</code> of that type and mark it as <code>@Primary</code> or, if you prefer the builder-based approach, define a <code>Jackson2ObjectMapperBuilder</code> <code>@Bean</code>. Note that, in either case, doing so disables all autoconfiguration of the <code>ObjectMapper</code>.

If you provide any <code>@Beans</code> of type <code>MappingJackson2HttpMessageConverter</code>, they replace the default value in the MVC configuration. Also, a convenience bean of type <code>HttpMessageConverters</code> is provided (and is always available if you use the default MVC configuration). It has some useful methods to access the default and user-enhanced message converters.

See the "<u>Section 77.4</u>, "<u>Customize the @ResponseBody Rendering</u>"" section and the <u>WebMvcAutoConfiguration</u> source code for more details.

77.4 Customize the @ResponseBody Rendering

Spring uses HttpMessageConverters to render @ResponseBody (or responses from @RestController). You can contribute additional converters by adding beans of the appropriate type in a Spring Boot context. If a bean you add is of a type that would have been included by default anyway (such as MappingJackson2HttpMessageConverter for JSON conversions), it replaces the default value. A convenience bean of type HttpMessageConverters is provided and is always available if you use the default MVC configuration. It has some useful methods to access the default and user-enhanced message converters (For example, it can be useful if you want to manually inject them into a custom RestTemplate).

As in normal MVC usage, any WebMvcConfigurer beans that you provide can also contribute converters by overriding the configureMessageConverters method. However, unlike with normal MVC, you can supply only additional converters that you need (because Spring Boot uses the same mechanism to contribute its defaults). Finally, if you opt out of the Spring Boot default MVC configuration by providing your own @EnableWebMvc configuration, you can take control completely and do everything manually by using getMessageConverters from WebMvcConfigurationSupport.

See the <u>WebMvcAutoConfiguration</u> source code for more details.

77.5 Handling Multipart File Uploads

Spring Boot embraces the Servlet 3 javax.servlet.http.Part API to support uploading files. By default, Spring Boot configures Spring MVC with a maximum size of 1MB per file and a maximum of 10MB of file data in a single request. You may override these values, the location to which intermediate data is stored (for example, to the /tmp directory), and the threshold past which data is flushed to disk by using the properties exposed in the MultipartProperties class. For example, if you want to specify that files be unlimited, set the spring.servlet.multipart.max-file-size property to -1.

The multipart support is helpful when you want to receive multipart encoded file data as a <code>@RequestParam-annotated</code> parameter of type <code>MultipartFile</code> in a Spring MVC controller handler method.

See the MultipartAutoConfiguration source for more details.

77.6 Switch Off the Spring MVC DispatcherServlet

Spring Boot wants to serve all content from the root of your application (/) down. If you would rather map your own servlet to that URL, you can do it. However, you may lose some of the other Boot MVC features. To add your own servlet and map it to the root resource, declare a @Bean of type Servlet and give it the special bean name, dispatcherServlet. (You can also create a bean of a different type with that name if you want to switch it off and not replace it.)

77.7 Switch off the Default MVC Configuration

The easiest way to take complete control over MVC configuration is to provide your own <code>@Configuration</code> with the <code>@EnableWebMvc</code> annotation. Doing so leaves all MVC configuration in your hands.

77.8 Customize ViewResolvers

A ViewResolver is a core component of Spring MVC, translating view names in @Controller to actual View implementations. Note that ViewResolvers are mainly used in UI applications, rather than REST-style services (a View is not used to render a @ResponseBody). There are many implementations of ViewResolver to choose from, and Spring on its own is not opinionated about which ones you should use. Spring Boot, on the other hand, installs one or two for you, depending on what it finds on the classpath and in the application context. The DispatcherServlet uses all the resolvers it finds in the application context, trying each one in turn until it gets a result, so, if you add your own, you have to be aware of the order and in which position your resolver is added.

WebMvcAutoConfiguration adds the following ViewResolvers to your context:

- An InternalResourceViewResolver named 'defaultViewResolver'. This one locates physical resources that can be rendered by using the DefaultServlet (including static resources and JSP pages, if you use those). It applies a prefix and a suffix to the view name and then looks for a physical resource with that path in the servlet context (the defaults are both empty but are accessible for external configuration through spring.mvc.view.prefix and spring.mvc.view.suffix). You can override it by providing a bean of the same type.
- A BeanNameViewResolver named 'beanNameViewResolver'. This is a useful member of the view
 resolver chain and picks up any beans with the same name as the View being resolved. It should
 not be necessary to override or replace it.
- A ContentNegotiatingViewResolver named 'viewResolver' is added only if there are actually beans of type View present. This is a 'master' resolver, delegating to all the others and attempting to find a match to the 'Accept' HTTP header sent by the client. There is a useful blog about ContentNegotiatingViewResolver that you might like to study to learn more, and you might also look at the source code for detail. You can switch off the auto-configured ContentNegotiatingViewResolver by defining a bean named 'viewResolver'.
- If you use Thymeleaf, you also have a ThymeleafViewResolver named 'thymeleafViewResolver'. It looks for resources by surrounding the view name with a prefix and suffix. The prefix is spring.thymeleaf.prefix, and the suffix is spring.thymeleaf.suffix. The values of the prefix and suffix default to 'classpath:/templates/' and '.html', respectively. You can override ThymeleafViewResolver by providing a bean of the same name.
- If you use FreeMarker, you also have a FreeMarkerViewResolver named 'freeMarkerViewResolver'. It looks for resources in a loader path (which is externalized to

spring.freemarker.templateLoaderPath and has a default value of 'classpath:/templates/') by surrounding the view name with a prefix and a suffix. The prefix is externalized to spring.freemarker.prefix, and the suffix is externalized to spring.freemarker.suffix. The default values of the prefix and suffix are empty and '.ftl', respectively. You can override FreeMarkerViewResolver by providing a bean of the same name.

• If you use Groovy templates (actually, if <code>groovy-templates</code> is on your classpath), you also have a <code>GroovyMarkupViewResolver</code> named 'groovyMarkupViewResolver'. It looks for resources in a loader path by surrounding the view name with a prefix and suffix (externalized to <code>spring.groovy.template.prefix</code> and <code>spring.groovy.template.suffix</code>). The prefix and suffix have default values of 'classpath:/templates/' and '.tpl', respectively. You can override <code>GroovyMarkupViewResolver</code> by providing a bean of the same name.

For more detail, see the following sections:

- WebMvcAutoConfiguration
- ThymeleafAutoConfiguration
- FreeMarkerAutoConfiguration
- <u>GroovyTemplateAutoConfiguration</u>

78. HTTP Clients

Spring Boot offers a number of starters that work with HTTP clients. This section answers questions related to using them.

78.1 Configure RestTemplate to Use a Proxy

As described in <u>Section 35.1</u>, <u>"RestTemplate Customization"</u>, you can use a RestTemplateCustomizer with RestTemplateBuilder to build a customized RestTemplate. This is the recommended approach for creating a RestTemplate configured to use a proxy.

The exact details of the proxy configuration depend on the underlying client request factory that is being used. The following example configures HttpComponentsClientRequestFactory with an HttpClient that uses a proxy for all hosts except 192.168.0.5:

```
static class ProxyCustomizer implements RestTemplateCustomizer {
 @Override
 public void customize(RestTemplate restTemplate) {
 HttpHost proxy = new HttpHost("proxy.example.com");
 HttpClient httpClient = HttpClientBuilder.create()
    .setRoutePlanner(new DefaultProxyRoutePlanner(proxy) {
    @Override
     public HttpHost determineProxy(HttpHost target,
      HttpRequest request, HttpContext context)
         throws HttpException {
      if (target.getHostName().equals("192.168.0.5")) {
      return null;
      return super.determineProxy(target, request, context);
    }).build();
  \verb"restTemplate.setRequestFactory" (
    new HttpComponentsClientHttpRequestFactory(httpClient));
```

79. Logging

Spring Boot has no mandatory logging dependency, except for the Commons Logging API, of which there are many implementations to choose from. To use Logback, you need to include it and jclover-slf4j (which implements the Commons Logging API) on the classpath. The simplest way to do that is through the starters, which all depend on spring-boot-starter-logging. For a web application, you need only spring-boot-starter-web, since it depends transitively on the logging starter. If you use Maven, the following dependency adds logging for you:

```
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-web</artifactId>
</dependency>
```

Spring Boot has a LoggingSystem abstraction that attempts to configure logging based on the content of the classpath. If Logback is available, it is the first choice.

If the only change you need to make to logging is to set the levels of various loggers, you can do so in application.properties by using the "logging.level" prefix, as shown in the following example:

```
logging.level.org.springframework.web=DEBUG logging.level.org.hibernate=ERROR
```

You can also set the location of a file to which to write the log (in addition to the console) by using "logging.file".

To configure the more fine-grained settings of a logging system, you need to use the native configuration format supported by the LoggingSystem in question. By default, Spring Boot picks up the native configuration from its default location for the system (such as classpath:logback.xml for Logback), but you can set the location of the config file by using the "logging.config" property.

79.1 Configure Logback for Logging

If you put a logback.xml in the root of your classpath, it is picked up from there (or from logback-spring.xml, to take advantage of the templating features provided by Boot). Spring Boot provides a default base configuration that you can include if you want to set levels, as shown in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration>
<include resource="org/springframework/boot/logging/logback/base.xml"/>
<logger name="org.springframework.web" level="DEBUG"/>
</configuration>
```

If you look at base.xml in the spring-boot jar, you can see that it uses some useful System properties that the LoggingSystem takes care of creating for you:

- \${PID}: The current process ID.
- \${LOG_FILE}: Whether logging.file was set in Boot's external configuration.
- \${LOG_PATH}: Whether logging.path (representing a directory for log files to live in) was set in Boot's external configuration.
- \${LOG_EXCEPTION_CONVERSION_WORD}: Whether logging.exception-conversion-word was set in Boot's external configuration.

Spring Boot also provides some nice ANSI color terminal output on a console (but not in a log file) by using a custom Logback converter. See the default base.xml configuration for details.

If Groovy is on the classpath, you should be able to configure Logback with logback.groovy as well. If present, this setting is given preference.

Configure Logback for File-only Output

If you want to disable console logging and write output only to a file, you need a custom logback-spring.xml that imports file-appender.xml but not console-appender.xml, as shown in the following example:

You also need to add logging.file to your application.properties, as shown in the following example:

```
logging.file=myapplication.log
```

79.2 Configure Log4j for Logging

Spring Boot supports <u>Log4j 2</u> for logging configuration if it is on the classpath. If you use the starters for assembling dependencies, you have to exclude Logback and then include log4j 2 instead. If you do not use the starters, you need to provide (at least) jcl-over-slf4j in addition to Log4j 2.

The simplest path is probably through the starters, even though it requires some jiggling with excludes. The following example shows how to set up the starters in Maven:

```
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-web</artifactId>
</dependency>
<groupId>org.springframework.boot
<artifactId>spring-boot-starter</artifactId>
<exclusions>
 <exclusion>
  <groupId>org.springframework.boot
  <artifactId>spring-boot-starter-logging</artifactId>
 </exclusion>
</exclusions>
</dependency>
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-log4j2</artifactId>
</dependency>
```

Note

The Log4j starters gather together the dependencies for common logging requirements (such as having Tomcat use <code>java.util.logging</code> but configuring the output using Log4j 2). See the Actuator Log4j 2 samples for more detail and to see it in action.

Use YAML or JSON to Configure Log4j 2

In addition to its default XML configuration format, Log4j 2 also supports YAML and JSON configuration files. To configure Log4j 2 to use an alternative configuration file format, add the appropriate dependencies to the classpath and name your configuration files to match your chosen file format, as shown in the following example:

Format	Dependencies	File names
YAML	<pre>com.fasterxml.jackson.core:jackson-databind com.fasterxml.jackson.dataformat:jackson-dataformat- yaml</pre>	log4j2.yaml
JSON	com.fasterxml.jackson.core:jackson-databind	log4j2.json

80. Data Access

Spring Boot includes a number of starters for working with data sources. This section answers questions related to doing so.

80.1 Configure a Custom DataSource

To configure your own DataSource, define a @Bean of that type in your configuration. Spring Boot reuses your DataSource anywhere one is required, including database initialization. If you need to externalize some settings, you can bind your DataSource to the environment (see "the section called "Third-party Configuration"").

The following example shows how to define a data source in a bean:

```
@Bean
@ConfigurationProperties(prefix="app.datasource")
public DataSource dataSource() {
  return new FancyDataSource();
}
```

The following example shows how to define a data source by setting properties:

```
app.datasource.url=jdbc:h2:mem:mydb
app.datasource.username=sa
app.datasource.pool-size=30
```

Assuming that your FancyDataSource has regular JavaBean properties for the URL, the username, and the pool size, these settings are bound automatically before the DataSource is made available to other components. The regular <u>database initialization</u> also happens (so the relevant sub-set of spring.datasource.* can still be used with your custom configuration).

You can apply the same principle if you configure a custom JNDI DataSource, as shown in the following example:

```
@Bean(destroyMethod="")
@ConfigurationProperties(prefix="app.datasource")
public DataSource dataSource() throws Exception {
   JndiDataSourceLookup dataSourceLookup = new JndiDataSourceLookup();
   return dataSourceLookup.getDataSource("java:comp/env/jdbc/YourDS");
}
```

Spring Boot also provides a utility builder class, called DataSourceBuilder, that can be used to create one of the standard data sources (if it is on the classpath). The builder can detect the one to use based on what's available on the classpath. It also auto-detects the driver based on the JDBC URL.

The following example shows how to create a data source by using a DataSourceBuilder:

```
@Bean
@ConfigurationProperties("app.datasource")
public DataSource dataSource() {
  return DataSourceBuilder.create().build();
}
```

To run an app with that DataSource, all you need is the connection information. Pool-specific settings can also be provided. Check the implementation that is going to be used at runtime for more details.

The following example shows how to define a JDBC data source by setting properties:

```
app.datasource.url=jdbc:mysql://localhost/test
app.datasource.username=dbuser
app.datasource.password=dbpass
app.datasource.pool-size=30
```

However, there is a catch. Because the actual type of the connection pool is not exposed, no keys are generated in the metadata for your custom <code>DataSource</code> and no completion is available in your IDE (because the <code>DataSource</code> interface exposes no properties). Also, if you happen to have Hikari on the classpath, this basic setup does not work, because Hikari has no <code>url</code> property (but does have a <code>jdbcUrl</code> property). In that case, you must rewrite your configuration as follows:

```
app.datasource.jdbc-url=jdbc:mysql://localhost/test
app.datasource.username=dbuser
app.datasource.password=dbpass
app.datasource.maximum-pool-size=30
```

You can fix that by forcing the connection pool to use and return a dedicated implementation rather than DataSource. You cannot change the implementation at runtime, but the list of options will be explicit.

The following example shows how create a HikariDataSource with DataSourceBuilder:

```
@Bean
@ConfigurationProperties("app.datasource")
public HikariDataSource dataSource() {
  return DataSourceBuilder.create().type(HikariDataSource.class).build();
}
```

You can even go further by leveraging what <code>DataSourceProperties</code> does for you—that is, by providing a default embedded database with a sensible username and password if no URL is provided. You can easily initialize a <code>DataSourceBuilder</code> from the state of any <code>DataSourceProperties</code> object, so you could also inject the <code>DataSource</code> that Spring Boot creates automatically. However, that would split your configuration into two namespaces: <code>url</code>, <code>username</code>, <code>password</code>, <code>type</code>, and <code>driver</code> on <code>spring.datasource</code> and the rest on your custom namespace (<code>app.datasource</code>). To avoid that, you can redefine a custom <code>DataSourceProperties</code> on your custom namespace, as shown in the following example:

```
@Bean
@Primary
@ConfigurationProperties("app.datasource")
public DataSourceProperties dataSourceProperties() {
    return new DataSourceProperties();
}

@Bean
@ConfigurationProperties("app.datasource")
public HikariDataSource dataSource(DataSourceProperties properties) {
    return properties.initializeDataSourceBuilder().type(HikariDataSource.class)
    .build();
}
```

This setup puts you *in sync* with what Spring Boot does for you by default, except that a dedicated connection pool is chosen (in code) and its settings are exposed in the same namespace. Because <code>DataSourceProperties</code> is taking care of the <code>url/jdbcUrl</code> translation for you, you can configure it as follows:

```
app.datasource.url=jdbc:mysql://localhost/test
app.datasource.username=dbuser
app.datasource.password=dbpass
app.datasource.maximum-pool-size=30
```

Note

Because your custom configuration chooses to go with Hikari, app.datasource.type has no effect. In practice, the builder is initialized with whatever value you might set there and then overridden by the call to .type().

See "<u>Section 31.1</u>, "<u>Configure a DataSource</u>"" in the "Spring Boot features" section and the <u>DataSourceAutoConfiguration</u> class for more details.

80.2 Configure Two DataSources

If you need to configure multiple data sources, you can apply the same tricks that are described in the previous section. You must, however, mark one of the DataSource instances as @Primary, because various auto-configurations down the road expect to be able to get one by type.

If you create your own DataSource, the auto-configuration backs off. In the following example, we provide the *exact* same feature set as the auto-configuration provides on the primary data source:

```
@Bean
@Primary
@ConfigurationProperties("app.datasource.first")
public DataSourceProperties firstDataSourceProperties() {
    return new DataSourceProperties();
}

@Bean
@Primary
@ConfigurationProperties("app.datasource.first")
public DataSource firstDataSource() {
    return firstDataSourceProperties().initializeDataSourceBuilder().build();
}

@Bean
@ConfigurationProperties("app.datasource.second")
public BasicDataSource secondDataSource() {
    return DataSourceBuilder.create().type(BasicDataSource.class).build();
}
```

Tip

firstDataSourceProperties has to be flagged as @Primary so that the database initializer feature uses your copy (if you use the initializer).

Both data sources are also bound for advanced customizations. For instance, you could configure them as follows:

```
app.datasource.first.type=com.zaxxer.hikari.HikariDataSource
app.datasource.first.maximum-pool-size=30

app.datasource.second.url=jdbc:mysql://localhost/test
app.datasource.second.username=dbuser
app.datasource.second.password=dbpass
app.datasource.second.max-total=30
```

You can apply the same concept to the secondary DataSource as well, as shown in the following example:

```
@Bean
@Primary
@ConfigurationProperties("app.datasource.first")
public DataSourceProperties firstDataSourceProperties() {
```

```
return new DataSourceProperties();
}

@Bean
@Primary
@ConfigurationProperties("app.datasource.first")
public DataSource firstDataSource() {
    return firstDataSourceProperties().initializeDataSourceBuilder().build();
}

@Bean
@ConfigurationProperties("app.datasource.second")
public DataSourceProperties secondDataSourceProperties() {
    return new DataSourceProperties();
}

@Bean
@ConfigurationProperties("app.datasource.second")
public DataSource secondDataSource() {
    return secondDataSourceProperties().initializeDataSourceBuilder().build();
}
```

The preceding example configures two data sources on custom namespaces with the same logic as Spring Boot would use in auto-configuration.

80.3 Use Spring Data Repositories

Spring Data can create implementations of <code>@Repository</code> interfaces of various flavors. Spring Boot handles all of that for you, as long as those <code>@Repositories</code> are included in the same package (or a sub-package) of your <code>@EnableAutoConfiguration</code> class.

For many applications, all you need is to put the right Spring Data dependencies on your classpath (there is a <code>spring-boot-starter-data-jpa</code> for JPA and a <code>spring-boot-starter-data-mongodb</code> for Mongodb) and create some repository interfaces to handle your <code>@Entity</code> objects. Examples are in the <u>JPA sample</u> and the <u>Mongodb sample</u>.

Spring Boot tries to guess the location of your @Repository definitions, based on the @EnableAutoConfiguration it finds. To get more control, use the @EnableJpaRepositories annotation (from Spring Data JPA).

For more about Spring Data, see the Spring Data project page.

80.4 Separate @Entity Definitions from Spring Configuration

Spring Boot tries to guess the location of your @Entity definitions, based on the @EnableAutoConfiguration it finds. To get more control, you can use the @EntityScan annotation, as shown in the following example:

```
@Configuration
@EnableAutoConfiguration
@EntityScan(basePackageClasses=City.class)
public class Application {
   //...
}
```

80.5 Configure JPA Properties

Spring Data JPA already provides some vendor-independent configuration options (such as those for SQL logging), and Spring Boot exposes those options and a few more for Hibernate as external

configuration properties. Some of them are automatically detected according to the context so you should not have to set them.

The spring.jpa.hibernate.ddl-auto is a special case, because, depending on runtime conditions, it has different defaults. If an embedded database is used and no schema manager (such as Liquibase or Flyway) is handling the DataSource, it defaults to create-drop. In all other cases, it defaults to none.

The dialect to use is also automatically detected based on the current DataSource, but you can set spring.jpa.database yourself if you want to be explicit and bypass that check on startup.

Note

Specifying a database leads to the configuration of a well-defined Hibernate dialect. Several databases have more than one Dialect, and this may not suit your needs. In that case, you can either set spring.jpa.database to default to let Hibernate figure things out or set the dialect by setting the spring.jpa.database-platform property.

The most common options to set are shown in the following example:

```
spring.jpa.hibernate.naming.physical-strategy=com.example.MyPhysicalNamingStrategy spring.jpa.show-sql=true
```

In addition, all properties in spring.jpa.properties.* are passed through as normal JPA properties (with the prefix stripped) when the local EntityManagerFactory is created.

Tip

If you need to apply advanced customization to Hibernate properties, consider registering a HibernatePropertiesCustomizer bean that will be invoked prior to creating the EntityManagerFactory. This takes precedence to anything that is applied by the autoconfiguration.

80.6 Configure Hibernate Naming Strategy

Hibernate uses two different naming strategies to map names from the object model to the corresponding database names. The fully qualified class name of the physical and the implicit strategy implementations can be configured by setting the spring.jpa.hibernate.naming.physical-strategy and spring.jpa.hibernate.naming.implicit-strategy properties, respectively. Alternatively, if ImplicitNamingStrategy or PhysicalNamingStrategy beans are available in the application context, Hibernate will be automatically configured to use them.

By default, Spring Boot configures the physical naming strategy with SpringPhysicalNamingStrategy. This implementation provides the same table structure as Hibernate 4: all dots are replaced by underscores and camel casing is replaced by underscores as well. By default, all table names are generated in lower case, but it is possible to override that flag if your schema requires it.

For example, a TelephoneNumber entity is mapped to the telephone_number table.

If you prefer to use Hibernate 5's default instead, set the following property:

```
spring.jpa.hibernate.naming.physical-strategy=org.hibernate.boot.model.naming.PhysicalNamingStrategyStandardImpl
```

Alternatively, you can configure the following bean:

```
@Bean
public PhysicalNamingStrategy physicalNamingStrategy() {
  return new PhysicalNamingStrategyStandardImpl();
}
```

See <u>HibernateJpaAutoConfiguration</u> and <u>JpaBaseConfiguration</u> for more details.

80.7 Use a Custom EntityManagerFactory

To take full control of the configuration of the EntityManagerFactory, you need to add a @Bean named 'entityManagerFactory'. Spring Boot auto-configuration switches off its entity manager in the presence of a bean of that type.

80.8 Use Two EntityManagers

Even if the default EntityManagerFactory works fine, you need to define a new one. Otherwise, the presence of the second bean of that type switches off the default. To make it easy to do, you can use the convenient EntityManagerBuilder provided by Spring Boot. Alternatively, you can just the LocalContainerEntityManagerFactoryBean directly from Spring ORM, as shown in the following example:

```
// add two data sources configured as above
public LocalContainerEntityManagerFactoryBean customerEntityManagerFactory(
 EntityManagerFactoryBuilder builder) {
return builder
   .dataSource(customerDataSource())
   .packages(Customer.class)
   .persistenceUnit("customers")
   .build();
public LocalContainerEntityManagerFactoryBean orderEntityManagerFactory(
 EntityManagerFactoryBuilder builder) {
return builder
   .dataSource(orderDataSource())
  .packages(Order.class)
   .persistenceUnit("orders")
   .build();
}
```

The configuration above almost works on its own. To complete the picture, you need to configure TransactionManagers for the two EntityManagers as well. If you mark one of them as @Primary, it could be picked up by the default JpaTransactionManager in Spring Boot. The other would have to be explicitly injected into a new instance. Alternatively, you might be able to use a JTA transaction manager that spans both.

If you use Spring Data, you need to configure @EnableJpaRepositories accordingly, as shown in the following example:

```
@Configuration
@EnableJpaRepositories(basePackageClasses = Customer.class,
entityManagerFactoryRef = "customerEntityManagerFactory")
public class CustomerConfiguration {
    ...
}
```

```
@Configuration
@EnableJpaRepositories(basePackageClasses = Order.class,
   entityManagerFactoryRef = "orderEntityManagerFactory")
public class OrderConfiguration {
    ...
}
```

80.9 Use a Traditional persistence.xml File

Spring does not require the use of XML to configure the JPA provider, and Spring Boot assumes you want to take advantage of that feature. If you prefer to use persistence.xml, you need to define your own @Bean of type LocalEntityManagerFactoryBean (with an ID of 'entityManagerFactory') and set the persistence unit name there.

See <u>JpaBaseConfiguration</u> for the default settings.

80.10 Use Spring Data JPA and Mongo Repositories

Spring Data JPA and Spring Data Mongo can both automatically create Repository implementations for you. If they are both present on the classpath, you might have to do some extra configuration to tell Spring Boot which repositories to create. The most explicit way to do that is to use the standard Spring Data @EnableJpaRepositories and @EnableMongoRepositories annotations and provide the location of your Repository interfaces.

There are also flags (spring.data.*.repositories.enabled and spring.data.*.repositories.type) that you can use to switch the auto-configured repositories on and off in external configuration. Doing so is useful, for instance, in case you want to switch off the Mongo repositories and still use the auto-configured MongoTemplate.

The same obstacle and the same features exist for other auto-configured Spring Data repository types (Elasticsearch, Solr, and others). To work with them, change the names of the annotations and flags accordingly.

80.11 Expose Spring Data Repositories as REST Endpoint

Spring Data REST can expose the Repository implementations as REST endpoints for you, provided Spring MVC has been enabled for the application.

Spring Boot exposes a set of useful properties (from the spring.data.rest namespace) that customize the RepositoryRestConfiguration. If you need to provide additional customization, you should use a RestConfigurer bean.

Note

If you do not specify any order on your custom RepositoryRestConfigurer, it runs after the one Spring Boot uses internally. If you need to specify an order, make sure it is higher than 0.

80.12 Configure a Component that is Used by JPA

If you want to configure a component that JPA uses, then you need to ensure that the component is initialized before JPA. When the component is auto-configured, Spring Boot takes care of this for you. For example, when Flyway is auto-configured, Hibernate is configured to depend upon Flyway so that Flyway has a chance to initialize the database before Hibernate tries to use it.

If you are configuring a component yourself, you can use an EntityManagerFactoryDependsOnPostProcessor subclass as a convenient way of setting up the necessary dependencies. For example, if you use Hibernate Search with Elasticsearch as its index manager, any EntityManagerFactory beans must be configured to depend on the elasticsearchClient bean, as shown in the following example:

```
/**
  * {@link EntityManagerFactoryDependsOnPostProcessor} that ensures that
  * {@link EntityManagerFactory} beans depend on the {@code elasticsearchClient} bean.
  */
  @Configuration
  static class ElasticsearchJpaDependencyConfiguration
  extends EntityManagerFactoryDependsOnPostProcessor {

ElasticsearchJpaDependencyConfiguration() {
  super("elasticsearchClient");
  }
}
```

80.13 Configure jOOQ with Two DataSources

If you need to use jOOQ with multiple data sources, you should create your own DSLContext for each one. Refer to $\underline{JooqAutoConfiguration}$ for more details.

Tip

In particular, JooqExceptionTranslator and SpringTransactionProvider can be reused to provide similar features to what the auto-configuration does with a single DataSource.

81. Database Initialization

An SQL database can be initialized in different ways depending on what your stack is. Of course, you can also do it manually, provided the database is a separate process.

81.1 Initialize a Database Using JPA

JPA has features for DDL generation, and these can be set up to run on startup against the database. This is controlled through two external properties:

- spring.jpa.generate-ddl (boolean) switches the feature on and off and is vendor independent.
- spring.jpa.hibernate.ddl-auto (enum) is a Hibernate feature that controls the behavior in a more fine-grained way. This feature is described in more detail later in this guide.

81.2 Initialize a Database Using Hibernate

You can set spring.jpa.hibernate.ddl-auto explicitly and the standard Hibernate property values are none, validate, update, create, and create-drop. Spring Boot chooses a default value for you based on whether it thinks your database is embedded. It defaults to create-drop if no schema manager has been detected or none in all other cases. An embedded database is detected by looking at the Connection type. hsqldb, h2, and derby are embedded, and others are not. Be careful when switching from in-memory to a 'real' database that you do not make assumptions about the existence of the tables and data in the new platform. You either have to set ddl-auto explicitly or use one of the other mechanisms to initialize the database.

Note

You can output the schema creation by enabling the org.hibernate.SQL logger. This is done for you automatically if you enable the <u>debug mode</u>.

In addition, a file named import.sql in the root of the classpath is executed on startup if Hibernate creates the schema from scratch (that is, if the ddl-auto property is set to create or create-drop). This can be useful for demos and for testing if you are careful but is probably not something you want to be on the classpath in production. It is a Hibernate feature (and has nothing to do with Spring).

81.3 Initialize a Database

Spring Boot can automatically create the schema (DDL scripts) of your DataSource and initialize it (DML scripts). It loads SQL from the standard root classpath locations: schema.sql and data.sql, respectively. In addition, Spring Boot processes the schema-\${platform}.sql and data-\${platform}.sql files (if present), where platform is the value of spring.datasource.platform. This allows you to switch to database-specific scripts if necessary. For example, you might choose to set it to the vendor name of the database (hsqldb, h2, oracle, mysql, postgresql, and so on).

Spring Boot automatically creates the schema of an embedded DataSource. This behavior can be customized by using the spring.datasource.initialization-mode property (and it can also be always or never).

By default, Spring Boot enables the fail-fast feature of the Spring JDBC initializer. This means that, if the scripts cause exceptions, the application fails to start. You can tune that behavior by setting spring.datasource.continue-on-error.

Note

In a JPA-based app, you can choose to let Hibernate create the schema or use schema.sql, but you cannot do both. Make sure to disable spring.jpa.hibernate.ddl-auto if you use schema.sql.

81.4 Initialize a Spring Batch Database

If you use Spring Batch, it comes pre-packaged with SQL initialization scripts for most popular database platforms. Spring Boot can detect your database type and execute those scripts on startup. If you use an embedded database, this happens by default. You can also enable it for any database type, as shown in the following example:

```
spring.batch.initialize-schema=always
```

You can also switch off the initialization explicitly by setting spring.batch.initialize-schema=never.

81.5 Use a Higher-level Database Migration Tool

Spring Boot supports two higher-level migration tools: Flyway and Liquibase.

Execute Flyway Database Migrations on Startup

To automatically run Flyway database migrations on startup, add the org.flywaydb:flyway-core to your classpath.

The migrations are scripts in the form V<VERSION>__<NAME>.sql (with <VERSION> an underscore-separated version, such as '1' or '2_1'). By default, they are in a folder called classpath:db/migration, but you can modify that location by setting spring.flyway.locations. You can also add a special {vendor} placeholder to use vendor-specific scripts. Assume the following:

```
spring.flyway.locations=db/migration/{vendor}
```

Rather than using db/migration, the preceding configuration sets the folder to use according to the type of the database (such as db/migration/mysql for MySQL). The list of supported databases is available in patabaseDriver.

See the Flyway class from flyway-core for details of available settings such as schemas and others. In addition, Spring Boot provides a small set of properties (in FlywayProperties) that can be used to disable the migrations or switch off the location checking. Spring Boot calls Flyway.migrate() to perform the database migration. If you would like more control, provide a @Bean that implements FlywayMigrationStrategy.

Flyway supports SQL and Java <u>callbacks</u>. To use SQL-based callbacks, place the callback scripts in the <code>classpath:db/migration</code> folder. To use Java-based callbacks, create one or more beans that implement <code>FlywayCallback</code> or, preferably, extend <code>BaseFlywayCallback</code>. Any such beans are automatically registered with <code>Flyway</code>. They can be ordered by using <code>@Order</code> or by implementing <code>Ordered</code>.

By default, Flyway autowires the (@Primary) DataSource in your context and uses that for migrations. If you like to use a different DataSource, you can create one and mark its @Bean as @FlywayDataSource. If you do so and want two data sources, remember to create another one and mark it as @Primary. Alternatively, you can use Flyway's native DataSource by setting spring.flyway.[url,user,password] in external properties.

There is a <u>Flyway sample</u> so that you can see how to set things up.

You can also use Flyway to provide data for specific scenarios. For example, you can place test-specific migrations in src/test/resources and they are run only when your application starts for testing. Also, you can use profile-specific configuration to customize spring.flyway.locations so that certain migrations run only when a particular profile is active. For example, in application-dev.properties, you might specify the following setting:

```
spring.flyway.locations=classpath:/db/migration,classpath:/dev/db/migration
```

With that setup, migrations in dev/db/migration run only when the dev profile is active.

Execute Liquibase Database Migrations on Startup

To automatically run Liquibase database migrations on startup, add the org.liquibase:liquibase-core to your classpath.

By default, the master change log is read from db/changelog/db.changelog-master.yaml, but you can change the location by setting spring.liquibase.change-log. In addition to YAML, Liquibase also supports JSON, XML, and SQL change log formats.

By default, Liquibase autowires the (@Primary) DataSource in your context and uses that for migrations. If you need to use a different DataSource, you can create one and mark its @Bean as @LiquibaseDataSource. If you do so and you want two data sources, remember to create another one and mark it as @Primary. Alternatively, you can use Liquibase's native DataSource by setting spring.liquibase.[url,user,password] in external properties.

See <u>LiquibaseProperties</u> for details about available settings such as contexts, the default schema, and others.

There is a <u>Liquibase sample</u> so that you can see how to set things up.

82. Messaging

Spring Boot offers a number of starters that include messaging. This section answers questions that arise from using messaging with Spring Boot.

82.1 Disable Transacted JMS Session

If your JMS broker does not support transacted sessions, you have to disable the support of transactions altogether. If you create your own <code>JmsListenerContainerFactory</code>, there is nothing to do, since, by default it cannot be transacted. If you want to use the <code>DefaultJmsListenerContainerFactoryConfigurer</code> to reuse Spring Boot's default, you can disable transacted sessions, as follows:

```
@Bean
public DefaultJmsListenerContainerFactory jmsListenerContainerFactory(
   ConnectionFactory connectionFactory,
   DefaultJmsListenerContainerFactoryConfigurer configurer) {
   DefaultJmsListenerContainerFactory listenerFactory =
        new DefaultJmsListenerContainerFactory();
   configurer.configure(listenerFactory, connectionFactory);
   listenerFactory.setTransactionManager(null);
   listenerFactory.setSessionTransacted(false);
   return listenerFactory;
}
```

The preceding example overrides the default factory, and it should be applied to any other factory that your application defines, if any.

83. Batch Applications

This section answers questions that arise from using Spring Batch with Spring Boot.

Note

By default, batch applications require a DataSource to store job details. If you want to deviate from that, you need to implement BatchConfigurer. See <u>The Javadoc of @EnableBatchProcessing</u> for more details.

For more about Spring Batch, see the Spring Batch project page.

83.1 Execute Spring Batch Jobs on Startup

Spring Batch auto-configuration is enabled by adding @EnableBatchProcessing (from Spring Batch) somewhere in your context.

By default, it executes **all** Jobs in the application context on startup (see <u>JobLauncherCommandLineRunner</u> for details). You can narrow down to a specific job or jobs by specifying spring.batch.job.names (which takes a comma-separated list of job name patterns).

If the application context includes a JobRegistry, the jobs in spring.batch.job.names are looked up in the registry instead of being autowired from the context. This is a common pattern with more complex systems, where multiple jobs are defined in child contexts and registered centrally.

See <u>BatchAutoConfiguration</u> and <u>@EnableBatchProcessing</u> for more details.

84. Actuator

Spring Boot includes the Spring Boot Actuator. This section answers questions that often arise from its use.

84.1 Change the HTTP Port or Address of the Actuator Endpoints

In a standalone application, the Actuator HTTP port defaults to the same as the main HTTP port. To make the application listen on a different port, set the external property: management.server.port. To listen on a completely different network address (such as when you have an internal network for management and an external one for user applications), you can also set management.server.address to a valid IP address to which the server is able to bind.

For more detail, see the <u>ManagementServerProperties</u> source code and "<u>Section 52.2</u>, "<u>Customizing the Management Server Port"</u>" in the "Production-ready features" section.

84.2 Customize the 'whitelabel' Error Page

Spring Boot installs a 'whitelabel' error page that you see in a browser client if you encounter a server error (machine clients consuming JSON and other media types should see a sensible response with the right error code).

Note

Set server.error.whitelabel.enabled=false to switch the default error page off. Doing so restores the default of the servlet container that you are using. Note that Spring Boot still tries to resolve the error view, so you should probably add your own error page rather than disabling it completely.

Overriding the error page with your own depends on the templating technology that you use. For example, if you use Thymeleaf, you can add an error.html template. If you use FreeMarker, you can add an error.ftl template. In general, you need a View that resolves with a name of error or a @Controller that handles the /error path. Unless you replaced some of the default configuration, you should find a BeanNameViewResolver in your ApplicationContext, so a @Bean named error would be a simple way of doing that. See ErrorMvcAutoConfiguration for more options.

See also the section on "Error Handling" for details of how to register handlers in the servlet container.

85. Security

This section addresses questions about security when working with Spring Boot, including questions that arise from using Spring Security with Spring Boot.

For more about Spring Security, see the Spring Security project page.

85.1 Switch off the Spring Boot Security Configuration

If you define a @Configuration with a WebSecurityConfigurerAdapter in your application, it switches off the default webapp security settings in Spring Boot.

85.2 Change the AuthenticationManager and Add User Accounts

If you provide a <code>@Bean</code> of type <code>AuthenticationManager</code>, <code>AuthenticationProvider</code>, or <code>UserDetailsService</code>, the default <code>@Bean</code> for <code>InMemoryUserDetailsManager</code> is not created, so you have the full feature set of Spring Security available (such as various authentication options).

The easiest way to add user accounts is to provide your own UserDetailsService bean.

85.3 Enable HTTPS When Running behind a Proxy Server

Ensuring that all your main endpoints are only available over HTTPS is an important chore for any application. If you use Tomcat as a servlet container, then Spring Boot adds Tomcat's own RemotelpValve automatically if it detects some environment settings, and you should be able to rely on the HttpServletRequest to report whether it is secure or not (even downstream of a proxy server that handles the real SSL termination). The standard behavior is determined by the presence or absence of certain request headers (x-forwarded-for and x-forwarded-proto), whose names are conventional, so it should work with most front-end proxies. You can switch on the valve by adding some entries to application.properties, as shown in the following example:

```
server.tomcat.remote-ip-header=x-forwarded-for
server.tomcat.protocol-header=x-forwarded-proto
```

(The presence of either of those properties switches on the valve. Alternatively, you can add the RemotelpValve by adding a TomcatServletWebServerFactory bean.)

To configure Spring Security to require a secure channel for all (or some) requests, consider adding your own WebSecurityConfigurerAdapter that adds the following HttpSecurity configuration:

```
@Configuration
public class SslWebSecurityConfigurerAdapter extends WebSecurityConfigurerAdapter {
    @Override
    protected void configure(HttpSecurity http) throws Exception {
        // Customize the application security
        http.requiresChannel().anyRequest().requiresSecure();
    }
}
```

86. Hot Swapping

Spring Boot supports hot swapping. This section answers questions about how it works.

86.1 Reload Static Content

There are several options for hot reloading. The recommended approach is to use spring-boot-devtools, as it provides additional development-time features, such as support for fast application restarts and LiveReload as well as sensible development-time configuration (such as template caching). Devtools works by monitoring the classpath for changes. This means that static resource changes must be "built" for the change to take affect. By default, this happens automatically in Eclipse when you save your changes. In IntelliJ IDEA, the Make Project command triggers the necessary build. Due to the default restart exclusions, changes to static resources do not trigger a restart of your application. They do, however, trigger a live reload.

Alternatively, running in an IDE (especially with debugging on) is a good way to do development (all modern IDEs allow reloading of static resources and usually also allow hot-swapping of Java class changes).

Finally, the <u>Maven and Gradle plugins</u> can be configured (see the addResources property) to support running from the command line with reloading of static files directly from source. You can use that with an external css/js compiler process if you are writing that code with higher-level tools.

86.2 Reload Templates without Restarting the Container

Most of the templating technologies supported by Spring Boot include a configuration option to disable caching (described later in this document). If you use the <code>spring-boot-devtools</code> module, these properties are <u>automatically configured</u> for you at development time.

Thymeleaf Templates

If you use Thymeleaf, set spring.thymeleaf.cache to false. See ThymeleafAutoConfiguration for other Thymeleaf customization options.

FreeMarker Templates

If you use FreeMarker, set spring.freemarker.cache to false. See FreeMarkerAutoConfiguration for other FreeMarker customization options.

Groovy Templates

If you use Groovy templates, set spring.groovy.template.cache to false. See GroovyTemplateAutoConfiguration for other Groovy customization options.

86.3 Fast Application Restarts

The spring-boot-devtools module includes support for automatic application restarts. While not as fast as technologies such as <u>JRebel</u> it is usually significantly faster than a "cold start". You should probably give it a try before investigating some of the more complex reload options discussed later in this document.

For more details, see the Chapter 20, Developer Tools section.

86.4 Reload Java Classes without Restarting the Container

Many modern IDEs (Eclipse, IDEA, and others) support hot swapping of bytecode. Consequently, if you make a change that does not affect class or method signatures, it should reload cleanly with no side effects.

87. Build

Spring Boot includes build plugins for Maven and Gradle. This section answers common questions about these plugins.

87.1 Generate Build Information

Both the Maven plugin and the Gradle plugin allow generating build information containing the coordinates, name, and version of the project. The plugins can also be configured to add additional properties through configuration. When such a file is present, Spring Boot auto-configures a BuildProperties bean.

To generate build information with Maven, add an execution for the build-info goal, as shown in the following example:

```
<build>
<plugins>
<plugins
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
<version>2.0.0.BUILD-SNAPSHOT</version>
<executions>
<execution>
<goals>
<goal>build-info</goal>
</execution>
</execution>
</execution>
</execution>
</execution>
</execution>
</execution>
</plugin>
</plugins>
</build>
```

Tip

See the **Spring Boot Maven Plugin documentation** for more details.

The following example does the same with Gradle:

```
springBoot {
buildInfo()
}
```

Additional properties can be added by using the DSL, as shown in the following example:

```
springBoot {
buildInfo {
  additionalProperties = [
  'acme': 'test'
  ]
}
```

87.2 Generate Git Information

Both Maven and Gradle allow generating a git.properties file containing information about the state of your git source code repository when the project was built.

For Maven users, the spring-boot-starter-parent POM includes a pre-configured plugin to generate a git.properties file. To use it, add the following declaration to your POM:

```
<build>
<plugins>
  <plugin>
    <groupId>pl.project13.maven</groupId>
    <artifactId>git-commit-id-plugin</artifactId>
    </plugin>
  </plugins>
</build>
```

Gradle users can achieve the same result by using the gradle-git-properties plugin, as shown in the following example:

```
plugins {
  id "com.gorylenko.gradle-git-properties" version "1.4.17"
}
```

Tip

The commit time in git.properties is expected to match the following format: yyyy-MM-dd'T'HH:mm:ssZ. This is the default format for both plugins listed above. Using this format lets the time be parsed into a Date and its format, when serialized to JSON, to be controlled by Jackson's date serialization configuration settings.

87.3 Customize Dependency Versions

If you use a Maven build that inherits directly or indirectly from <code>spring-boot-dependencies</code> (for instance, <code>spring-boot-starter-parent</code>) but you want to override a specific third-party dependency, you can add appropriate <code>spring-boot-dependencies</code> POM for a complete list of properties. For example, to pick a different <code>slf4j</code> version, you would add the following property:

```
< <slf4j.version>1.7.5<slf4j.version>
```

Note

Doing so only works if your Maven project inherits (directly or indirectly) from spring-boot-dependencies. If you have added spring-boot-dependencies in your own dependencyManagement section with <scope>import</scope>, you have to redefine the artifact yourself instead of overriding the property.

Warning

Each Spring Boot release is designed and tested against this specific set of third-party dependencies. Overriding versions may cause compatibility issues.

87.4 Create an Executable JAR with Maven

The spring-boot-maven-plugin can be used to create an executable "fat" JAR. If you use the spring-boot-starter-parent POM, you can declare the plugin and your jars are repackaged as follows:

```
<build>
```

```
<plugins>
  <plugin>
   <groupId>org.springframework.boot</groupId>
   <artifactId>spring-boot-maven-plugin</artifactId>
   </plugin>
  </plugins>
</build>
```

If you do not use the parent POM, you can still use the plugin. However, you must additionally add an <executions> section, as follows:

```
<build>
  <plugins>
  <plugin>
   <groupId>org.springframework.boot</groupId>
   <artifactId>spring-boot-maven-plugin</artifactId>
   <version>2.0.0.BUILD-SNAPSHOT</version>
   <executions>
   <execution>
   <goals>
      <goal>repackage</goal>
      </goals>
      </execution>
   </execution>
   </execution>
   </execution>
   </execution>
   </plugin>
   </plugins>
</build>
```

See the <u>plugin documentation</u> for full usage details.

87.5 Use a Spring Boot Application as a Dependency

Like a war file, a Spring Boot application is not intended to be used as a dependency. If your application contains classes that you want to share with other projects, the recommended approach is to move that code into a separate module. The separate module can then be depended upon by your application and other projects.

If you cannot rearrange your code as recommended above, Spring Boot's Maven and Gradle plugins must be configured to produce a separate artifact that is suitable for use as a dependency. The executable archive cannot be used as a dependency as the <u>executable jar format</u> packages application classes in BOOT-INF/classes. This means that they cannot be found when the executable jar is used as a dependency.

To produce the two artifacts, one that can be used as a dependency and one that is executable, a classifier must be specified. This classifier is applied to the name of the executable archive, leaving the default archive for use as a dependency.

To configure a classifier of exec in Maven, you can use the following configuration:

```
<build>
  <plugins>
  <plugin>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-maven-plugin</artifactId>
    <configuration>
        <classifier>exec</classifier>
        </configuration>
        </plugins>
    </build>
```

87.6 Extract Specific Libraries When an Executable Jar Runs

Most nested libraries in an executable jar do not need to be unpacked in order to run. However, certain libraries can have problems. For example, JRuby includes its own nested jar support, which assumes that the <code>jruby-complete.jar</code> is always directly available as a file in its own right.

To deal with any problematic libraries, you can flag that specific nested jars should be automatically unpacked to the "temp folder" when the executable jar first runs.

For example, to indicate that JRuby should be flagged for unpacking by using the Maven Plugin, you would add the following configuration:

```
<build>
<plugins>
 <plugin>
  <groupId>org.springframework.boot
  <artifactId>spring-boot-maven-plugin</artifactId>
  <configuration>
   <requiresUnpack>
    <dependency>
     <groupId>org.jruby</groupId>
     <artifactId>jruby-complete</artifactId>
    </dependency>
   </requiresUnpack>
  </configuration>
 </plugin>
</plugins>
</build>
```

87.7 Create a Non-executable JAR with Exclusions

Often, if you have an executable and a non-executable jar as two separate build products, the executable version has additional configuration files that are not needed in a library jar. For example, the application.yml configuration file might by excluded from the non-executable JAR.

In Maven, the executable jar must be the main artifact and you can add a classified jar for the library, as follows:

```
<build>
<plugins>
 <plugin>
  <groupId>org.springframework.boot
  <artifactId>spring-boot-mayen-plugin</artifactId>
 </plugin>
 <plugin>
  <artifactId>maven-jar-plugin</artifactId>
  <executions>
    <execution>
    <id>lib</id>
    <phase>package</phase>
    <goals>
     <goal>jar</goal>
    </goals>
    <configuration>
     <classifier>lib</classifier>
     <excludes>
      <exclude>application.yml</exclude>
     </excludes>
    </configuration>
   </execution>
  </executions>
 </plugin>
</plugins>
</build>
```

87.8 Remote Debug a Spring Boot Application Started with Mayen

To attach a remote debugger to a Spring Boot application that was started with Maven, you can use the jvmArguments property of the maven plugin.

See this example for more details.

87.9 Build an Executable Archive from Ant without Using spring-boot-antlib

To build with Ant, you need to grab dependencies, compile, and then create a jar or war archive. To make it executable, you can either use the spring-boot-antlib module or you can follow these instructions:

- 1. If you are building a jar, package the application's classes and resources in a nested BOOT-INF/classes directory. If you are building a war, package the application's classes in a nested WEB-INF/classes directory as usual.
- 2. Add the runtime dependencies in a nested BOOT-INF/lib directory for a jar or WEB-INF/lib for a war. Remember **not** to compress the entries in the archive.
- 3. Add the provided (embedded container) dependencies in a nested BOOT-INF/lib directory for a jar or WEB-INF/lib-provided for a war. Remember **not** to compress the entries in the archive.
- 4. Add the spring-boot-loader classes at the root of the archive (so that the Main-Class is available).
- 5. Use the appropriate launcher (such as <code>JarLauncher</code> for a jar file) as a <code>Main-Class</code> attribute in the manifest and specify the other properties it needs as manifest entries principally, by setting a <code>Start-Class</code> property.

The following example shows how to build an executable archive with Ant:

```
<target name="build" depends="compile">
<jar destfile="target/${ant.project.name}-${spring-boot.version}.jar" compress="false">
 <mappedresources>
  <fileset dir="target/classes" />
  <globmapper from="*" to="BOOT-INF/classes/*"/>
 </mappedresources>
 <mappedresources>
  <fileset dir="src/main/resources" erroronmissingdir="false"/>
  <globmapper from="*" to="BOOT-INF/classes/*"/>
 <mappedresources>
  <fileset dir="${lib.dir}/runtime" />
  <globmapper from="*" to="BOOT-INF/lib/*"/>
 </mappedresources>
 <zipfileset src="${lib.dir}/loader/spring-boot-loader-jar-${spring-boot.version}.jar" />
  <attribute name="Main-Class" value="org.springframework.boot.loader.JarLauncher" />
   <attribute name="Start-Class" value="${start-class}" />
 </manifest>
</jar>
</target>
```

The Ant Sample has a build.xml file with a manual task that should work if you run it with the following command:

\$ ant -lib <folder containing ivy-2.2.jar> clean manual

Then you can run the application with the following command:

\$ java -jar target/*.jar

88. Traditional Deployment

Spring Boot supports traditional deployment as well as more modern forms of deployment. This section answers common questions about traditional deployment.

88.1 Create a Deployable War File

The first step in producing a deployable war file is to provide a SpringBootServletInitializer subclass and override its configure method. Doing so makes use of Spring Framework's Servlet 3.0 support and lets you configure your application when it is launched by the servlet container. Typically, you should update your application's main class to extend SpringBootServletInitializer, as shown in the following example:

```
@SpringBootApplication
public class Application extends SpringBootServletInitializer {

@Override
protected SpringApplicationBuilder configure(SpringApplicationBuilder application) {
   return application.sources(Application.class);
}

public static void main(String[] args) throws Exception {
   SpringApplication.run(Application.class, args);
}
```

The next step is to update your build configuration such that your project produces a war file rather than a jar file. If you use Maven and spring-boot-starter-parent (which configures Maven's war plugin for you), all you need to do is to modify pom.xml to change the packaging to war, as follows:

```
<packaging>war</packaging>
```

If you use Gradle, you need to modify build.gradle to apply the war plugin to the project, as follows:

```
apply plugin: 'war'
```

The final step in the process is to ensure that the embedded servlet container does not interfere with the servlet container to which the war file is deployed. To do so, you need to mark the embedded servlet container dependency as being provided.

If you use Maven, the following example marks the servlet container (Tomcat, in this case) as being provided:

```
<dependencies>
<!-- ... -->
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-tomcat</artifactId>
  <scope>provided</scope>
</dependency>
<!-- ... -->
</dependencies>
```

If you use Gradle, the following example marks the servlet container (Tomcat, in this case) as being provided:

```
dependencies {
   // ...
   providedRuntime 'org.springframework.boot:spring-boot-starter-tomcat'
```

```
// ...
}
```

Tip

providedRuntime is preferred to Gradle's compileOnly configuration. Among other limitations, compileOnly dependencies are not on the test classpath, so any web-based integration tests fail.

If you use the <u>Spring Boot build tools</u>, marking the embedded servlet container dependency as provided produces an executable war file with the provided dependencies packaged in a <code>lib-provided</code> directory. This means that, in addition to being deployable to a servlet container, you can also run your application by using <code>java -jar</code> on the command line.

Tip

Take a look at Spring Boot's sample applications for a <u>Maven-based example</u> of the previously described configuration.

88.2 Create a Deployable War File for Older Servlet Containers

Older Servlet containers do not have support for the ServletContextInitializer bootstrap process used in Servlet 3.0. You can still use Spring and Spring Boot in these containers, but you are going to need to add a web.xml to your application and configure it to load an ApplicationContext via a DispatcherServlet.

88.3 Convert an Existing Application to Spring Boot

For a non-web application, it should be easy to convert an existing Spring application to a Spring Boot application. To do so, throw away the code that creates your ApplicationContext and replace it with calls to SpringApplication or SpringApplicationBuilder. Spring MVC web applications are generally amenable to first creating a deployable war application and then migrating it later to an executable war or jar. See the <u>Getting Started Guide on Converting a jar to a war</u>.

To create a deployable war by extending <code>SpringBootServletInitializer</code> (for example, in a class called <code>Application</code>) and adding the <code>SpringBootApplication</code> annotation, use code similar to that shown in the following example:

```
@SpringBootApplication
public class Application extends SpringBootServletInitializer {

@Override
protected SpringApplicationBuilder configure(SpringApplicationBuilder application) {

// Customize the application or call application.sources(...) to add sources

// Since our example is itself a @Configuration class (via @SpringBootApplication)

// we actually don't need to override this method.
return application;
}

}
```

Remember that, whatever you put in the sources is merely a Spring ApplicationContext. Normally, anything that already works should work here. There might be some beans you can remove later and let Spring Boot provide its own defaults for them, but it should be possible to get something working before you need to do that.

Static resources can be moved to /public (or /static or /resources or /META-INF/resources) in the classpath root. The same applies to messages.properties (which Spring Boot automatically detects in the root of the classpath).

Vanilla usage of Spring DispatcherServlet and Spring Security should require no further changes. If you have other features in your application (for instance, using other servlets or filters), you may need to add some configuration to your Application context, by replacing those elements from the web.xml, as follows:

- A @Bean of type Servlet or ServletRegistrationBean installs that bean in the container as if it were a <servlet/> and <servlet-mapping/> in web.xml.
- A @Bean of type Filter or FilterRegistrationBean behaves similarly (as a <filter/> and <filter-mapping/>).
- An ApplicationContext in an XML file can be added through an @ImportResource in your Application. Alternatively, simple cases where annotation configuration is heavily used already can be recreated in a few lines as @Bean definitions.

Once the war file is working, you can make it executable by adding a main method to your Application, as shown in the following example:

```
public static void main(String[] args) {
   SpringApplication.run(Application.class, args);
}
```

Note

If you intend to start your application as a war or as an executable application, you need to share the customizations of the builder in a method that is both available to the SpringBootServletInitializer callback and in the main method in a class similar to the following:

```
@SpringBootApplication
public class Application extends SpringBootServletInitializer {

@Override
protected SpringApplicationBuilder configure(SpringApplicationBuilder builder) {
    return configureApplication(builder);
}

public static void main(String[] args) {
    configureApplication(new SpringApplicationBuilder()).run(args);
}

private static SpringApplicationBuilder configureApplication(SpringApplicationBuilder) {
    return builder.sources(Application.class).bannerMode(Banner.Mode.OFF);
}

}
```

Applications can fall into more than one category:

- Servlet 3.0+ applications with no web.xml.
- Applications with a web.xml.
- Applications with a context hierarchy.

· Applications without a context hierarchy.

All of these should be amenable to translation, but each might require slightly different techniques.

Servlet 3.0+ applications might translate pretty easily if they already use the Spring Servlet 3.0+ initializer support classes. Normally, all the code from an existing WebApplicationInitializer can be moved into a SpringBootServletInitializer. If your existing application has more than one ApplicationContext (for example, if it uses AbstractDispatcherServletInitializer) then you might be able to combine all your context sources into a single SpringApplication. The main complication you might encounter is if combining does not work and you need to maintain the context hierarchy. See the entry on building a hierarchy for examples. An existing parent context that contains web-specific features usually needs to be broken up so that all the ServletContextAware components are in the child context.

Applications that are not already Spring applications might be convertible to Spring Boot applications, and the previously mentioned guidance may help. However, you may yet encounter problems. In that case, we suggest asking questions on Stack Overflow with a tag of spring-boot.

88.4 Deploying a WAR to WebLogic

To deploy a Spring Boot application to WebLogic, you must ensure that your servlet initializer **directly** implements WebApplicationInitializer (even if you extend from a base class that already implements it).

A typical initializer for WebLogic should resemble the following example:

```
import org.springframework.boot.autoconfigure.SpringBootApplication;
import org.springframework.boot.web.servlet.support.SpringBootServletInitializer;
import org.springframework.web.WebApplicationInitializer;

@SpringBootApplication
public class MyApplication extends SpringBootServletInitializer implements WebApplicationInitializer {
}
```

If you use Logback, you also need to tell WebLogic to prefer the packaged version rather than the version that was pre-installed with the server. You can do so by adding a WEB-INF/weblogic.xml file with the following contents:

```
<?xml version="1.0" encoding="UTF-8"?>
<wls:weblogic-web-app
xmlns:wls="http://xmlns.oracle.com/weblogic/weblogic-web-app"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd
http://xmlns.oracle.com/weblogic/weblogic-web-app
http://xmlns.oracle.com/weblogic/weblogic-web-app/1.4/weblogic-web-app.xsd">
<wls:container-descriptor>
<wls:prefer-application-packages>
    <wls:package-name>org.slf4j</wls:package-name>
    </wls:container-descriptor>
</wls:container-descriptor>
</wls:veblogic-web-app>
```

88.5 Deploying a WAR in an Old (Servlet 2.5) Container

Spring Boot uses Servlet 3.0 APIs to initialize the ServletContext (register Servlets and so on), so you cannot use the same application in a Servlet 2.5 container. It **is**, however, possible to run a Spring Boot application on an older container with some special tools. If you include

org.springframework.boot:spring-boot-legacy as a dependency (maintained separately to the core of Spring Boot and currently available at 1.1.0.RELEASE), all you need to do is create a web.xml and declare a context listener to create the application context and your filters and servlets. The context listener is a special purpose one for Spring Boot, but the rest of it is normal for a Spring application in Servlet 2.5. The following Maven example shows how to set up a Spring Boot project to run in a Servlet 2.5 container:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app version="2.5" xmlns="http://java.sun.com/xml/ns/javaee"</pre>
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-
app 2 5.xsd">
<context-param>
 <param-name>contextConfigLocation</param-name>
 <param-value>demo.Application</param-value>
stener>
 </p
</listener>
<filter>
 <filter-name>metricsFilter</filter-name>
 <filter-class>org.springframework.web.filter.DelegatingFilterProxy</filter-class>
<filter-mapping>
 <filter-name>metricsFilter</filter-name>
 <url-pattern>/*</url-pattern>
</filter-mapping>
 <servlet-name>appServlet</servlet-name>
 <servlet-class>org.springframework.web.servlet.DispatcherServlet/servlet-class>
  <param-name>contextAttribute</param-name>
  <param-value>org.springframework.web.context.WebApplicationContext.ROOT</param-value>
 </init-param>
 <load-on-startup>1</load-on-startup>
</servlet>
<servlet-mapping>
 <servlet-name>appServlet
 <url-pattern>/</url-pattern>
</servlet-mapping>
</web-app>
```

In the preceding example, we use a single application context (the one created by the context listener) and attach it to the <code>DispatcherServlet</code> by using an <code>init</code> parameter. This is normal in a Spring Boot application (you normally only have one application context).

88.6 Use Jedis Instead of Lettuce

By default, the Spring Boot starter (spring-boot-starter-data-redis) uses <u>Lettuce</u>. You need to exclude that dependency and include the <u>Jedis</u> one instead. Spring Boot manages these dependencies to help make this process as easy as possible.

The following example shows how to do so in Maven:

```
<dependency>
  <groupId>org.springframework.boot</groupId>
```

```
<artifactId>spring-boot-starter-data-redis</artifactId>
<exclusions>
  <exclusion>
    <groupId>io.lettuce</groupId>
        <artifactId>lettuce-core</artifactId>
        </exclusion>
        </exclusions>
        </dependency>
        <dependency>
            <groupId>redis.clients</groupId>
            <artifactId>jedis</artifactId>
        </dependency>
        <dependency>
        </dependency>
        </dependency>
        </dependency>
</dependency>
</dependency>
</dependency>
</dependency>
</dependency>
</dependency>
</dependency>
```

The following example shows how to do so in Gradle:

```
configurations {
  compile.exclude module: "lettuce"
}
dependencies {
  compile("redis.clients:jedis")
  // ...
}
```

Part X. Appendices

Appendix A. Common application properties

Various properties can be specified inside your application.properties file, inside your application.yml file, or as command line switches. This appendix provides a list of common Spring Boot properties and references to the underlying classes that consume them.

Note

Property contributions can come from additional jar files on your classpath, so you should not consider this an exhaustive list. Also, you can define your own properties.

Warning

This sample file is meant as a guide only. Do **not** copy and paste the entire content into your application. Rather, pick only the properties that you need.

```
# COMMON SPRING BOOT PROPERTIES
# This sample file is provided as a guideline. Do NOT copy it in its
# entirety to your own application. ^^^
# CORE PROPERTIES
logging.config= # Location of the logging configuration file. For instance, `classpath:logback.xml` for
logging.exception-conversion-word=%wEx # Conversion word used when logging exceptions.
logging.file= # Log file name. For instance, `myapp.log`
logging.file.max-history= # Maximum of archive log files to keep. Only supported with the default
logback setup.
logging.file.max-size= # Maximum log file size. Only supported with the default logback setup.
logging.level.*= # Log levels severity mapping. For instance, `logging.level.org.springframework=DEBUG`
logging.path= # Location of the log file. For instance, `/var/log`
logging.pattern.console= # Appender pattern for output to the console. Supported only with the default
Logback setup.
logging.pattern.dateformat=yyyy-MM-dd HH:mm:ss.SSS # Appender pattern for log date format. Supported
only with the default Logback setup.
logging.pattern.file= # Appender pattern for output to a file. Supported only with the default Logback
logging.pattern.level= # Appender pattern for log level (default: %5p). Supported only with the default
logging.register-shutdown-hook-false # Register a shutdown hook for the logging system when it is
initialized.
# AOP
spring.aop.auto=true # Add @EnableAspectJAutoProxy.
spring.aop.proxy-target-class=true # Whether subclass-based (CGLIB) proxies are to be created (true), as
opposed to standard Java interface-based proxies (false).
# IDENTITY (ContextIdApplicationContextInitializer)
spring.application.name= # Application name.
# ADMIN (SpringApplicationAdminJmxAutoConfiguration)
spring.application.admin.enabled=false # Whether to enable admin features for the application.
```

```
spring.application.admin.jmx-name=org.springframework.boot:type=Admin,name=SpringApplication # JMX name
of the application admin MBean.
# AUTO-CONFIGURATION
spring.autoconfigure.exclude= # Auto-configuration classes to exclude.
spring.banner.charset=UTF-8 # Banner file encoding.
spring.banner.location=classpath:banner.txt # Banner file location.
spring.banner.image.location=classpath:banner.gif # Banner image file location (ipg or png can also be
spring.banner.image.width= # Width of the banner image in chars (default 76)
spring.banner.image.height= # Height of the banner image in chars (default based on image height)
spring.banner.image.margin= # Left hand image margin in chars (default 2)
spring.banner.image.invert= # Whether images should be inverted for dark terminal themes (default false)
# SPRING CORE
spring.beaninfo.ignore=true # Whether to skip search of BeanInfo classes.
# SPRING CACHE (CacheProperties)
spring.cache.cache-names= # Comma-separated list of cache names to create if supported by the underlying
cache manager.
spring.cache.caffeine.spec= # The spec to use to create caches. See CaffeineSpec for more details on the
spring.cache.couchbase.expiration=0ms # Entry expiration in milliseconds. By default, the entries never
spring.cache.ehcache.config= # The location of the configuration file to use to initialize EhCache.
spring.cache.infinispan.config= # The location of the configuration file to use to initialize
spring.cache.jcache.config= # The location of the configuration file to use to initialize the cache
spring.cache.jcache.provider= # Fully qualified name of the CachingProvider implementation to use to
retrieve the JSR-107 compliant cache manager. Needed only if more than one JSR-107 implementation is
available on the classpath.
spring.cache.redis.cache-null-values=true # Allow caching null values.
spring.cache.redis.key-prefix= # Key prefix.
spring.cache.redis.time-to-live=0ms # Entry expiration. By default the entries never expire.

```

Appendix B. Configuration Metadata

Spring Boot jars include metadata files that provide details of all supported configuration properties. The files are designed to let IDE developers offer contextual help and "code completion" as users are working with application.properties or application.yml files.

The majority of the metadata file is generated automatically at compile time by processing all items annotated with <code>@ConfigurationProperties</code>. However, it is possible to <u>write part of the metadata manually</u> for corner cases or more advanced use cases.

B.1 Metadata Format

Configuration metadata files are located inside jars under META-INF/spring-configuration-metadata.json They use a simple JSON format with items categorized under either "groups" or "properties" and additional values hints categorized under "hints", as shown in the following example:

```
{"groups": [
 "type": "org.springframework.boot.autoconfigure.web.ServerProperties",
 "sourceType" "org.springframework.boot.autoconfigure.web.ServerProperties"
 "name": "spring.jpa.hibernate",
 "type": "org.springframework.boot.autoconfigure.orm.jpa.JpaProperties$Hibernate",
 "sourceType": "org.springframework.boot.autoconfigure.orm.jpa.JpaProperties",
 "sourceMethod": "getHibernate()"
],"properties": [
 "name": "server.port",
 "type": "java.lang.Integer",
 "sourceType": "org.springframework.boot.autoconfigure.web.ServerProperties"
 "name": "server.servlet.path".
 "type": "java.lang.String",
 "sourceType": "org.springframework.boot.autoconfigure.web.ServerProperties",
 "defaultValue": "/"
},
   "name": "spring.jpa.hibernate.ddl-auto",
   "type": "java.lang.String",
   "description": "DDL mode. This is actually a shortcut for the \"hibernate.hbm2ddl.auto\" property.",
   "sourceType": "org.springframework.boot.autoconfigure.orm.jpa.JpaProperties$Hibernate"
| "hints": [
 "name": "spring.jpa.hibernate.ddl-auto",
 "values": [
   "description": "Disable DDL handling."
   "value": "validate",
   "description": "Validate the schema, make no changes to the database."
   "value": "update",
   "description": "Update the schema if necessary."
```

```
{
  "value": "create",
  "description": "Create the schema and destroy previous data."
},
{
  "value": "create-drop",
  "description": "Create and then destroy the schema at the end of the session."
}
]
}
```

Each "property" is a configuration item that the user specifies with a given value. For example, server.port and server.servlet.path might be specified in application.properties, as follows:

```
server.port=9090
server.servlet.path=/home
```

The "groups" are higher level items that do not themselves specify a value but instead provide a contextual grouping for properties. For example, the server.port and server.servlet.path properties are part of the server group.

Note

It is not required that every "property" has a "group". Some properties might exist in their own right.

Finally, "hints" are additional information used to assist the user in configuring a given property. For example, when a developer is configuring the <code>spring.jpa.hibernate.ddl-auto</code> property, a tool can use the hints to offer some auto-completion help for the <code>none</code>, <code>validate</code>, <code>update</code>, <code>create</code>, and <code>create-drop</code> values.

Group Attributes

The JSON object contained in the groups array can contain the attributes shown in the following table:

Name	Туре	Purpose	
name	String	The full name of the group. This attribute is mandatory.	
type	String	The class name of the data type of the group. For example, if the group were based on a class annotated with <code>@ConfigurationProperties</code> , the attribute would contain the fully qualified name of that class. If it were based on a <code>@Bean</code> method, it would be the return type of that method. If the type is not known, the attribute may be omitted.	
description	String	A short description of the group that can be displayed to users. not description is available, it may be omitted. It is recommended that descriptions be short paragraphs, with the first line providing a concise summary. The last line in the description should end with a period (.).	
sourceType	String	The class name of the source that contributed this group. For example, if the group were based on a @Bean method annotated	

Name	Туре	Purpose	
		with @ConfigurationProperties, this attribute would contain the fully qualified name of the @Configuration class that contains the method. If the source type is not known, the attribute may be omitted.	
sourceMethod	String	The full name of the method (include parenthesis and argumentypes) that contributed this group (for example, the name of a @ConfigurationProperties annotated @Bean method). If source method is not known, it may be omitted.	

Property Attributes

The JSON object contained in the properties array can contain the attributes described in the following table:

Name	Туре	Purpose		
name	String	The full name of the property. Names are in lower-case period- separated form (for example, server.servlet.path). This attribute is mandatory.		
type	String	The full signature of the data type of the property (for example, java.lang.String) but also a full generic type (such as java.util.Map <java.util.string,acme.myenum>). You can use this attribute to guide the user as to the types of values that they can enter. For consistency, the type of a primitive is specified by using its wrapper counterpart (for example, boole becomes java.lang.Boolean). Note that this class may be complex type that gets converted from a String as values are bound. If the type is not known, it may be omitted.</java.util.string,acme.myenum>		
description	String	A short description of the group that can be displayed to users. If no description is available, it may be omitted. It is recommended that descriptions be short paragraphs, with the first line providing a concise summary. The last line in the description should end with a period (.).		
sourceType	String	The class name of the source that contributed this property. For example, if the property were from a class annotated with <code>@ConfigurationProperties</code> , this attribute would contain the fully qualified name of that class. If the source type is unknown, it may be omitted.		
defaultValue	Object	The default value, which is used if the property is not specified. If the type of the property is an array, it can be an array of value(s). If the default value is unknown, it may be omitted.		
deprecation	Deprecation	Specify whether the property is deprecated. If the field is not deprecated or if that information is not known, it may be omitted. The next table offers more detail about the deprecation attribute.		

The JSON object contained in the deprecation attribute of each properties element can contain the following attributes:

Name	Туре	Purpose	
level	String	The level of deprecation, which can be either warning (the default) or error. When a property has a warning deprecation level, it should still be bound in the environment. However, when it has an error deprecation level, the property is no longer managed and is not bound.	
reason	String	A short description of the reason why the property was deprecated. If no reason is available, it may be omitted. It is recommended that descriptions be short paragraphs, with the first line providing a concise summary. The last line in the description should end with a period (.).	
replacement	String	The full name of the property that <i>replaces</i> this deprecated property. If there is no replacement for this property, it may be omitted.	

Note

Prior to Spring Boot 1.3, a single deprecated boolean attribute can be used instead of the deprecation element. This is still supported in a deprecated fashion and should no longer be used. If no reason and replacement are available, an empty deprecation object should be set.

Deprecation can also be specified declaratively in code by adding the <code>@DeprecatedConfigurationProperty</code> annotation to the getter exposing the deprecated property. For instance, assume that the <code>app.acme.target</code> property was confusing and was renamed to <code>app.acme.name</code>. The following example shows how to handle that situation:

```
@ConfigurationProperties("app.acme")
public class AcmeProperties {
  private String name;
  public String getName() { ... }
  public void setName(String name) { ... }
  @DeprecatedConfigurationProperty(replacement = "app.acme.name")
  @Deprecated
  public String getTarget() {
    return getName();
  }
  @Deprecated
  public void setTarget(String target) {
    setName(target);
  }
}
```

Note

There is no way to set a level. warning is always assumed, since code is still handling the property.

The preceding code makes sure that the deprecated property still works (delegating to the name property behind the scenes). Once the <code>getTarget</code> and <code>setTarget</code> methods can be removed from your public API, the automatic deprecation hint in the metadata goes away as well. If you want to keep a hint, adding manual metadata with an <code>error</code> deprecation level ensures that users are still informed about that property. Doing so is particularly useful when a <code>replacement</code> is provided.

Hint Attributes

The JSON object contained in the hints array can contain the attributes shown in the following table:

Name	Туре	Purpose	
name	String	The full name of the property to which this hint refers. Names are in lower-case period-separated form (such as server.servlet.path). If the property refers to a map (such as system.contexts), the hint either applies to the keys of the map (system.context.keys) or the values (system.context.values) of the map. This attribute is mandatory.	
values	ValueHint[]	A list of valid values as defined by the ValueHint object (described in the next table). Each entry defines the value and may have a description.	
providers	ValueProvider[]	A list of providers as defined by the ValueProvider object (described later in this document). Each entry defines the name of the provider and its parameters, if any.	

The JSON object contained in the values attribute of each hint element can contain the attributes described in the following table:

Name	Туре	Purpose	
value	Object	A valid value for the element to which the hint refers. If the type of the property is an array, it can also be an array of value(s). This attribute is mandatory.	
description	String	A short description of the value that can be displayed to users. If no description is available, it may be omitted. It is recommended that descriptions be short paragraphs, with the first line providing a concise summary. The last line in the description should end with a period (.).	

The JSON object contained in the providers attribute of each hint element can contain the attributes described in the following table:

Name	Туре	Purpose	
name	String	The name of the provider to use to offer additional content assistance for the element to which the hint refers.	

Name	Туре	Purpose	
parameters	JSON object	Any additional parameter that the provider supports (check the documentation of the provider for more details).	

Repeated Metadata Items

Objects with the same "property" and "group" name can appear multiple times within a metadata file. For example, you could bind two separate classes to the same prefix, with each having potentially overlapping property names. While the same names appearing in the metadata multiple times should not be common, consumers of metadata should take care to ensure that they support it.

B.2 Providing Manual Hints

To improve the user experience and further assist the user in configuring a given property, you can provide additional metadata that:

- Describes the list of potential values for a property.
- Associates a provider, to attach a well defined semantic to a property, so that a tool can discover the
 list of potential values based on the project's context.

Value Hint

The name attribute of each hint refers to the name of a property. In the <u>initial example shown earlier</u>, we provide five values for the spring.jpa.hibernate.ddl-auto property: none, validate, update, create, and create-drop. Each value may have a description as well.

If your property is of type Map, you can provide hints for both the keys and the values (but not for the map itself). The special .keys and .values suffixes must refer to the keys and the values, respectively.

Assume a sample.contexts maps magic String values to an integer, as shown in the following example:

```
@ConfigurationProperties("sample")
public class SampleProperties {

   private Map<String,Integer> contexts;
   // getters and setters
}
```

The magic values are (in this example) are sample1 and sample2. In order to offer additional content assistance for the keys, you could add the following JSON to the manual metadata of the module:

Tip

We recommend that you use an Enum for those two values instead. If your IDE supports it, this is by far the most effective approach to auto-completion.

Value Providers

Providers are a powerful way to attach semantics to a property. In this section, we define the official providers that you can use for your own hints. However, your favorite IDE may implement some of these or none of them. Also, it could eventually provide its own.

Note

As this is a new feature, IDE vendors must catch up with how it works. Adoption times naturally vary.

The following table summarizes the list of supported providers:

Name	Description
any	Permits any additional value to be provided.
class-reference	Auto-completes the classes available in the project. Usually constrained by a base class that is specified by the target parameter.
handle-as	Handles the property as if it were defined by the type defined by the mandatory target parameter.
logger-name	Auto-completes valid logger names. Typically, package and class names available in the current project can be auto-completed.
spring-bean-reference	Auto-completes the available bean names in the current project. Usually constrained by a base class that is specified by the target parameter.
spring-profile-name	Auto-completes the available Spring profile names in the project.

Tip

Only one provider can be active for a given property, but you can specify several providers if they can all manage the property *in some way*. Make sure to place the most powerful provider first, as the IDE must use the first one in the JSON section that it can handle. If no provider for a given property is supported, no special content assistance is provided, either.

Any

The special **any** provider value permits any additional values to be provided. Regular value validation based on the property type should be applied if this is supported.

This provider is typically used if you have a list of values and any extra values should still be considered as valid.

The following example offers on and off as auto-completion values for system.state:

Note that, in the preceding example, any other value is also allowed.

Class Reference

The **class-reference** provider auto-completes classes available in the project. This provider supports the following parameters:

Parameter	Туре	Default value	Description
target	String (Class)	none	The fully qualified name of the class that should be assignable to the chosen value. Typically used to filter out-non candidate classes. Note that this information can be provided by the type itself by exposing a class with the appropriate upper bound.
concrete	boolean	true	Specify whether only concrete classes are to be considered as valid candidates.

The following metadata snippet corresponds to the standard server.servlet.jsp.class-name property that defines the JspServlet class name to use:

Handle As

The **handle-as** provider lets you substitute the type of the property to a more high-level type. This typically happens when the property has a java.lang.String type, because you do not want your

configuration classes to rely on classes that may not be on the classpath. This provider supports the following parameters:

Parameter	Туре	Default value	Description
target	String (Class)	none	The fully qualified name of the type to consider for the property. This parameter is mandatory.

The following types can be used:

- Any java.lang.Enum: Lists the possible values for the property. (We recommend defining the property with the Enum type, as no further hint should be required for the IDE to auto-complete the values.)
- java.nio.charset.Charset: Supports auto-completion of charset/encoding values (such as UTF-8)
- java.util.Locale: auto-completion of locales (such as en_US)
- org.springframework.util.MimeType: Supports auto-completion of content type values (such as text/plain)
- org.springframework.core.io.Resource: Supports auto-completion of Spring's Resource abstraction to refer to a file on the filesystem or on the classpath. (such as classpath:/sample.properties)

Tip

If multiple values can be provided, use a Collection or Array type to teach the IDE about it.

The following metadata snippet corresponds to the standard <code>spring.liquibase.change-log</code> property that defines the path to the changelog to use. It is actually used internally as a <code>org.springframework.core.io.Resource</code> but cannot be exposed as such, because we need to keep the original String value to pass it to the Liquibase API.

Logger Name

The **logger-name** provider auto-completes valid logger names. Typically, package and class names available in the current project can be auto-completed. Specific frameworks may have extra magic logger names that can be supported as well.

Since a logger name can be any arbitrary name, this provider should allow any value but could highlight valid package and class names that are not available in the project's classpath.

The following metadata snippet corresponds to the standard logging.level property. Keys are *logger* names, and values correspond to the standard log levels or any custom level.

```
{"hints": [
  "name": "logging.level.keys",
  "values": [
   "description": "Root logger used to assign the default logging level."
  ],
  "providers": [
    "name": "logger-name"
  "name": "logging.level.values",
    "value": "trace"
  },
    "value": "debug"
  },
    "value": "info"
    "value": "warn"
    "value": "error"
  },
    "value": "fatal"
    "value": "off"
  ],
  "providers": [
    "name": "any"
]}
```

Spring Bean Reference

The **spring-bean-reference** provider auto-completes the beans that are defined in the configuration of the current project. This provider supports the following parameters:

Parameter	Туре	Default value	Description
target	String (Class)	none	The fully qualified name of the bean class that should be assignable to the candidate. Typically used to filter out non-candidate beans.

The following metadata snippet corresponds to the standard spring.jmx.server property that defines the name of the MBeanServer bean to use:

```
{"hints": [
{
    "name": "spring.jmx.server",
    "providers": [
    {
        "name": "spring-bean-reference",
        "parameters": {
        "target": "javax.management.MBeanServer"
    }
    }
}
```

Note

The binder is not aware of the metadata. If you provide that hint, you still need to transform the bean name into an actual Bean reference using by the ApplicationContext.

Spring Profile Name

The **spring-profile-name** provider auto-completes the Spring profiles that are defined in the configuration of the current project.

The following metadata snippet corresponds to the standard spring.profiles.active property that defines the name of the Spring profile(s) to enable:

B.3 Generating Your Own Metadata by Using the Annotation Processor

You can easily generate your own configuration metadata file from items annotated with <code>@ConfigurationProperties</code> by using the <code>spring-boot-configuration-processor</code> jar. The jar includes a Java annotation processor which is invoked as your project is compiled. To use the processor, include <code>spring-boot-configuration-processor</code> as an optional dependency. For example, with Maven, you can add:

```
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-configuration-processor</artifactId>
  <optional>true</optional>
  </dependency>
```

With Gradle, you can use the <u>propdeps-plugin</u> and specify the following dependency:

```
dependencies {
  optional "org.springframework.boot:spring-boot-configuration-processor"
}
compileJava.dependsOn(processResources)
```

Note

You need to add <code>compileJava.dependsOn(processResources)</code> to your build to ensure that resources are processed before code is compiled. Without this directive, any <code>additional-spring-configuration-metadata.json</code> files are not processed.

The processor picks up both classes and methods that are annotated with <code>@ConfigurationProperties</code>. The Javadoc for field values within configuration classes is used to populate the description attribute.

Note

You should only use simple text with @ConfigurationProperties field Javadoc, since they are not processed before being added to the JSON.

Properties are discovered through the presence of standard getters and setters with special handling for collection types (that is detected even if only a getter is present). The annotation processor also supports the use of the <code>@Data</code>, <code>@Getter</code>, and <code>@Setter</code> lombok annotations.

Note

If you are using AspectJ in your project, you need to make sure that the annotation processor runs only once. There are several ways to do this. With Maven, you can configure the maven-apt-plugin explicitly and add the dependency to the annotation processor only there. You could also let the AspectJ plugin run all the processing and disable annotation processing in the maven-compiler-plugin configuration, as follows:

Nested Properties

The annotation processor automatically considers inner classes as nested properties. Consider the following class:

```
@ConfigurationProperties(prefix="server")
public class ServerProperties {

private String name;

private Host host;

// ... getter and setters

private static class Host {

private String ip;

private int port;

// ... getter and setters
}
```

}

The preceding example produces metadata information for server.name, server.host.ip, and server.host.port properties. You can use the @NestedConfigurationProperty annotation on a field to indicate that a regular (non-inner) class should be treated as if it were nested.

Tip

This has no effect on collections and maps, as those types are automatically identified, and a single metadata property is generated for each of them.

Adding Additional Metadata

Spring Boot's configuration file handling is quite flexible, and it is often the case that properties may exist that are not bound to a <code>@ConfigurationProperties</code> bean. You may also need to tune some attributes of an existing key. To support such cases and let you provide custom "hints", the annotation processor automatically merges items from <code>META-INF/additional-spring-configuration-metadata.json</code> into the main metadata file.

If you refer to a property that has been detected automatically, the description, default value, and deprecation information are overridden, if specified. If the manual property declaration is not identified in the current module, it is added as a new property.

The format of the additional-spring-configuration-metadata.json file is exactly the same as the regular spring-configuration-metadata.json. The additional properties file is optional. If you do not have any additional properties, do not add the file.

Appendix C. Auto-configuration classes

Here is a list of all auto-configuration classes provided by Spring Boot, with links to documentation and source code. Remember to also look at the conditions report in your application for more details of which features are switched on. (To do so, start the app with --debug or -Ddebug or, in an Actuator application, use the conditions endpoint).

C.1 From the "spring-boot-autoconfigure" module

The following auto-configuration classes are from the spring-boot-autoconfigure module:

Configuration Class	Links

	org.springframework.boot.autoconfigure.context.M
	org.springframework.boot.autoconfigure.validatio
	org.springframework.boot.autoconfigure.web.react
	org.springframework.boot.test.autoconfigure.web.
@WebMvcTest	org.springframework.boot.autoconfigure.cache.Cac
	org.springframework.boot.autoconfigure.context.M
	org.springframework.boot.autoconfigure.freemarke
	org.springframework.boot.autoconfigure.groovy.te
	org.springframework.boot.autoconfigure.gson.Gson
	org.springframework.boot.autoconfigure.hateoas.H
	org.springframework.boot.autoconfigure.http.Http
	org.springframework.boot.autoconfigure.jackson.J
	org.springframework.boot.autoconfigure.jsonb.Jso
	org.springframework.boot.autoconfigure.mustache.
	org.springframework.boot.autoconfigure.thymeleaf
	org.springframework.boot.autoconfigure.validatio
	org.springframework.boot.autoconfigure.web.servl
	org.springframework.boot.autoconfigure.web.servl
	org.springframework.boot.test.autoconfigure.web.
	org.springframework.boot.test.autoconfigure.web.

Test slice	Imported auto-configuration
	org.springframework.boot.test.autoconfigure.web.org.springframework.boot.test.autoconfigure.web.

Appendix E. The Executable Jar Format

The spring-boot-loader modules lets Spring Boot support executable jar and war files. If you use the Maven plugin or the Gradle plugin, executable jars are automatically generated, and you generally do not need to know the details of how they work.

If you need to create executable jars from a different build system or if you are just curious about the underlying technology, this section provides some background.

E.1 Nested JARs

Java does not provide any standard way to load nested jar files (that is, jar files that are themselves contained within a jar). This can be problematic if you need to distribute a self-contained application that can be run from the command line without unpacking.

To solve this problem, many developers use "shaded" jars. A shaded jar packages all classes, from all jars, into a single "uber jar". The problem with shaded jars is that it becomes hard to see which libraries are actually in your application. It can also be problematic if the same filename is used (but with different content) in multiple jars. Spring Boot takes a different approach and lets you actually nest jars directly.

The Executable Jar File Structure

Spring Boot Loader-compatible jar files should be structured in the following way:

```
example.jar
|
+-META-INF
| +-MANIFEST.MF
+-org
| +-springframework
| +-boot
| +-loader
| +-(spring boot loader classes)
+-BOOT-INF
+-classes
| +-mycompany
| +-project
| +-YourClasses.class
+-lib
+-dependency1.jar
+-dependency2.jar
```

Application classes should be placed in a nested BOOT-INF/classes directory. Dependencies should be placed in a nested BOOT-INF/lib directory.

The Executable War File Structure

Spring Boot Loader-compatible war files should be structured in the following way:

```
example.war

|
+-META-INF
| +-MANIFEST.MF
+-org
| +-springframework
```

```
| +-boot
| +-loader
| +-<spring boot loader classes>
+-WEB-INF
+-classes
| +-com
| +-mycompany
| +-project
| +-YourClasses.class
+-lib
| +-dependency1.jar
| +-dependency2.jar
+-lib-provided
+-servlet-api.jar
+-dependency3.jar
```

Dependencies should be placed in a nested WEB-INF/lib directory. Any dependencies that are required when running embedded but are not required when deploying to a traditional web container should be placed in WEB-INF/lib-provided.

E.2 Spring Boot's "JarFile" Class

The core class used to support loading nested jars is org.springframework.boot.loader.jar.JarFile. It lets you load jar content from a standard jar file or from nested child jar data. When first loaded, the location of each JarEntry is mapped to a physical file offset of the outer jar, as shown in the following example:

The preceding example shows how A.class can be found in /BOOT-INF/classes in myapp.jar at position 0063. B.class from the nested jar can actually be found in myapp.jar at position 3452, and C.class is at position 3980.

Armed with this information, we can load specific nested entries by seeking to the appropriate part of the outer jar. We do not need to unpack the archive, and we do not need to read all entry data into memory.

Compatibility with the Standard Java "JarFile"

Spring Boot Loader strives to remain compatible with existing code and libraries. org.springframework.boot.loader.jar.JarFile extends from java.util.jar.JarFile and should work as a drop-in replacement. The getURL() method returns a URL that opens a connection compatible with java.net.JarURLConnection and can be used with Java's URLClassLoader.

E.3 Launching Executable Jars

The org.springframework.boot.loader.Launcher class is a special bootstrap class that is used as an executable jar's main entry point. It is the actual Main-Class in your jar file, and it is used to setup an appropriate URLClassLoader and ultimately call your main() method.

Their purpose is to load resources (.class files and so on.) from nested jar files or war files in directories (as opposed to those explicitly on the classpath). In the case of JarLauncher and WarLauncher, the nested paths are fixed. JarLauncher looks in BOOT-INF/lib/, and WarLauncher looks in WEB-INF/lib/ and WEB-INF/lib-provided/. You can add extra jars in those locations if you want more. The PropertiesLauncher looks in BOOT-INF/lib/ in your application archive by default, but you can add additional locations by setting an environment variable called LOADER_PATH or loader.path in loader.properties (which is a comma-separated list of directories, archives, or directories within archives).

Launcher Manifest

You need to specify an appropriate Launcher as the Main-Class attribute of META-INF/MANIFEST.MF. The actual class that you want to launch (that is, the class that contains a main method) should be specified in the Start-Class attribute.

The following example shows a typical MANIFEST.MF for an executable jar file:

```
Main-Class: org.springframework.boot.loader.JarLauncher
Start-Class: com.mycompany.project.MyApplication
```

For a war file, it would be as follows:

```
Main-Class: org.springframework.boot.loader.WarLauncher
Start-Class: com.mycompany.project.MyApplication
```

Note

You need not specify Class-Path entries in your manifest file. The classpath is deduced from the nested jars.

Exploded Archives

Certain PaaS implementations may choose to unpack archives before they run. For example, Cloud Foundry operates this way. You can run an unpacked archive by starting the appropriate launcher, as follows:

```
$ unzip -q myapp.jar
$ java org.springframework.boot.loader.JarLauncher
```

E.4 PropertiesLauncher Features

PropertiesLauncher has a few special features that can be enabled with external properties (System properties, environment variables, manifest entries, or loader.properties). The following table describes these properties:

Key	Purpose
loader.path	Comma-separated Classpath, such as lib, \${HOME}/app/lib. Earlier entries take precedence, like a regular -classpath on the javac command line.

Key	Purpose
loader.home	Used to resolve relative paths in loader.path. For example, given loader.path=lib, then \${loader.home}/lib is a classpath location (along with all jar files in that directory). This property is also used to locate a loader.properties file, as in the following example /opt/app It defaults to \${user.dir}.
loader.args	Default arguments for the main method (space separated).
loader.main	Name of main class to launch (for example, com.app.Application).
loader.config.name	Name of properties file (for example, launcher) It defaults to loader.
loader.config.location	Path to properties file (for example, classpath:loader.properties). It defaults to loader.properties.
loader.system	Boolean flag to indicate that all properties should be added to System properties It defaults to false.

When specified as environment variables or manifest entries, the following names should be used:

Key	Manifest entry	Environment variable
loader.path	Loader-Path	LOADER_PATH
loader.home	Loader-Home	LOADER_HOME
loader.args	Loader-Args	LOADER_ARGS
loader.main	Start-Class	LOADER_MAIN
loader.config.location	Loader-Config-Location	LOADER_CONFIG_LOCATION
loader.system	Loader-System	LOADER_SYSTEM

Tip

Build plugins automatically move the Main-Class attribute to Start-Class when the fat jar is built. If you use that, specify the name of the class to launch by using the Main-Class attribute and leaving out Start-Class.

The following rules apply to working with PropertiesLauncher:

- loader.properties is searched for in loader.home, then in the root of the classpath, and then in classpath:/BOOT-INF/classes. The first location where a file with that name exists is used.
- loader.home is the directory location of an additional properties file (overriding the default) only when loader.config.location is not specified.

- loader.path can contain directories (which are scanned recursively for jar and zip files), archive paths, a directory within an archive that is scanned for jar files (for example, dependencies.jar!/lib), or wildcard patterns (for the default JVM behavior). Archive paths can be relative to loader.home or anywhere in the file system with a jar:file: prefix.
- loader.path (if empty) defaults to BOOT-INF/lib (meaning a local directory or a nested one if running from an archive). Because of this, PropertiesLauncher behaves the same as JarLauncher when no additional configuration is provided.
- loader.path can not be used to configure the location of loader.properties (the classpath used to search for the latter is the JVM classpath when PropertiesLauncher is launched).
- Placeholder replacement is done from System and environment variables plus the properties file itself on all values before use.
- The search order for properties (where it makes sense to look in more than one place) is environment variables, system properties, loader.properties, the exploded archive manifest, and the archive manifest.

E.5 Executable Jar Restrictions

You need to consider the following restrictions when working with a Spring Boot Loader packaged application:

- Zip entry compression: The ZipEntry for a nested jar must be saved by using the ZipEntry. STORED method. This is required so that we can seek directly to individual content within the nested jar. The content of the nested jar file itself can still be compressed, as can any other entries in the outer jar.
- System classLoader: Launched applications should use Thread.getContextClassLoader() when loading classes (most libraries and frameworks do so by default). Trying to load nested jar classes with ClassLoader.getSystemClassLoader() fails.java.util.Logging always uses the system classloader. For this reason, you should consider a different logging implementation.

E.6 Alternative Single Jar Solutions

If the preceding restrictions mean that you cannot use Spring Boot Loader, consider the following alternatives:

- Maven Shade Plugin
- JarClassLoader
- OneJar

Appendix F. Dependency versions

The following table provides details of all of the dependency versions that are provided by Spring Boot in its CLI (Command Line Interface), Maven dependency management, and Gradle plugin. When you declare a dependency on one of these artifacts without declaring a version, the version listed in the table is used.

Group ID	Artifact ID	Version
antlr	antlr	2.7.7
